

## Potential Hidden Extensions of Gold Breccia Pipes at Colosseum

Dateline Resources Limited (ASX: DTR, OTC: DTREF) is pleased to provide an update on commencement of additional exploration at the Colosseum Project in California, USA. Recent field mapping and geochemical sampling of felsite (rhyolite) outcrops located west and southwest of the Colosseum open pits have returned encouraging geochemical anomalies, potentially confirming the extension of the mineralized footprint.

### Highlights

- **Tangible evidence of a broader mineralized system at Colosseum** - Points to potential for hidden gold zones beyond historical workings.
- **Substantial exploration upside now clearly emerging** - Felsite outcrops analysed west and southwest of the Colosseum pits warrant follow up to determine the feasibility of mining an extended mineralized system.
- **Orientation matches the breccia pipe system and modelled felsite body** - Analysed felsite dykes structurally aligned with known mineralized trends
- **Multi-element pathfinders in felsite samples** - Antimony (Sb), Bismuth (Bi), and Tellurium (Te) presence suggests mineralizing system potential.
- **Geochemistry points to an intrusion-related gold system (IRGS)** - Signature Bi-Te-Sb halo consistent with a distal position within a vertically zoned system.
- **Surface results mirror top zones of known IRGS-style breccia pipes** - Supports theory that gold-rich core may exist at depth below current exposures.
- **All 641 historic drillholes targeted only the breccia pipes with surface exposure.**
- **Large areas of the property remain effectively untested** - No comprehensive geochemical program ever completed across the claims.
- **Rare Earths (REE) project bolstered by potential larger Gold deposit** – REE exploration plan on track to be reviewed to be completed early June.

## Field Sampling Results and Interpretation

The recent field program focused on mapping and sampling silicic felsite outcrops approximately 200–900 meters west and southwest of the Colosseum open pits.

Significantly, the felsite is enriched in pathfinder elements – namely As, Sb, and Bi – relative to typical background levels. This geochemical association is characteristic of the outer halos of an intrusion-related gold system (IRGS). In IRGS deposits, elements including silver, antimony, bismuth, and tellurium commonly form distal halos while gold is concentrated in the central zones. Thus, the presence of this pathfinder suite (coupled with nominal gold) suggests that these outcrops represent a distal geochemical footprint of the Colosseum mineral system. It indicates that the mineralizing system extends beyond the previously defined area, with its peripheral signature detectable at surface.

## Structural Alignment with Geological Model

Fig. 7. Sketch view from Interstate I-15 northwards to the Colosseum Area. Width of view about 3 miles.

Fig. 8. Semicircular nature of the rhyolite-breccia complex at Colosseum, with overall control on 310°-040° fractures with pipes developed at nodes at intersections. Potential area for further pipes or veins at depth is stippled.

Fig. 9. Possible cross-section of Colosseum.

Fig. 10. Idealised cut-away view of a stepped (trap-door) ring-complex dyke.

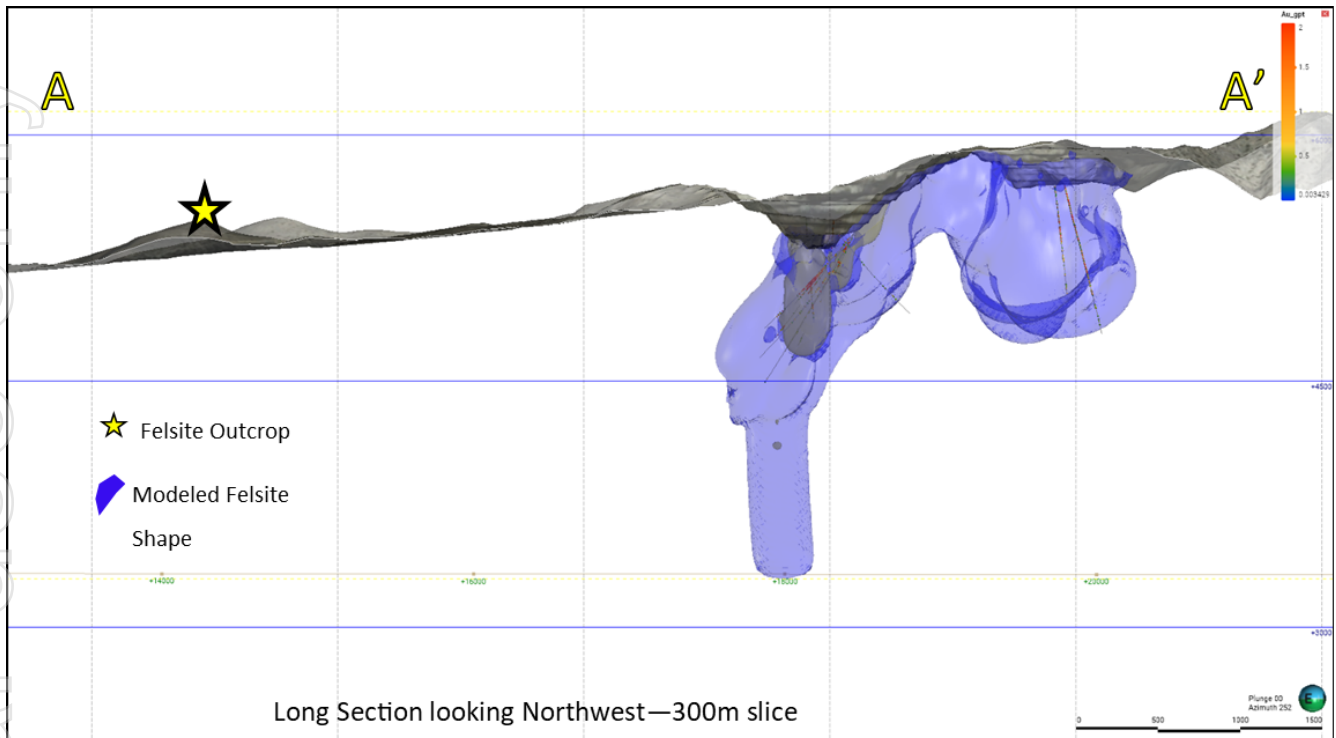

**Figure 1:** Surface mapping prior to open-pit mining, illustrating the semi-circular pattern of felsite (rhyolite) breccia. Source: Geology Notes, 1983.

Geological mapping has confirmed that the orientation of the newly exposed felsite dykes corresponds to the established structural framework of the Colosseum deposit. Historically, gold mineralization at Colosseum was controlled by a pronounced orthogonal fracture system and a ring-dyke pattern associated with an underlying intrusive body. The felsite outcrops analysed to the west and southwest occur along these same structural trends, suggesting they are part of the broader intrusive complex that gave rise to the breccia pipe orebodies, see Figure 1.

This structural alignment is significant. It demonstrates that the felsite (the likely intrusive driver of the system) extends beyond the pit boundaries. In effect, the outcropping dykes expand the known mineralized corridor and validate the historic geological model, which inferred a laterally extensive felsite intrusion and concentric fractures, on strike with the area of past mining. The consistency in orientation and rock type between the new outcrops and the modelled subsurface felsite supports the interpretation that these dykes are satellites to the main intrusion, potentially feeding additional breccia-style mineralization in the vicinity, see Figure 2 and Figure 3.

**Figure 2:** Plan view showing felsite outcrops, modelled felsite shape from north and south Colosseum Pits

**Figure 3:** Long section showing felsite outcrops, modelled felsite shape from north and south Colosseum Pits.

### Geochemical Characteristics and Alteration

Detailed geochemical analysis of the felsite samples provides insight into the nature of the mineralizing magma. Geochemically, the Colosseum felsite is indicative of a highly fractionated, moderately oxidized granitic melt. Evidence of extensive fractional crystallization is observed in the presence of abundant zircon (zirconium-rich accessory minerals) in thin section, implying the magma evolved and concentrated certain incompatible elements like Bi and Te over time. The concurrent presence of magnetite as an early crystallizing oxide phase suggests the magma had a relatively elevated oxidation state (though not as oxidized as typical porphyry systems, consistent with IRGS granites).

Alteration signatures in the felsite are well-developed. Major and trace element ratios (for example, high  $K_2O/Na_2O$  and elevated illite–sericite indices) confirm intense potassic and phyllic alteration. Potassic alteration (e.g. secondary K-feldspar and biotite) and phyllic alteration (widespread sericite-quartz-pyrite overprint) are both evident, indicating that the felsite dykes channelled significant hydrothermal fluids, see Figure 4.

The enrichment of bismuth and tellurium in the geochemical assays is particularly noteworthy, as these elements are commonly associated with gold in IRGS deposits (often in bismuth-telluride minerals accompanying gold). Their anomalous levels in the sampled felsite reinforce the interpretation that, while these surface exposures are geochemically distal, they lie within a fertile intrusive system capable of generating robust gold mineralization at depth. In summary, the geochemical and alteration profile of the felsite matches what would be expected in the outer zone of an intrusion-related gold system, adding credence to the possibility of a large, zoned mineralizing system at Colosseum.

**Figure 4:** Photograph shows a large, ~2-meter-wide felsite dyke oriented to the SW in the same orientation as the north and south Colosseum pits. Felsite dyke also exhibits alteration patterns consistent with felsite within the Colosseum gold breccia pipes.

### Exploration Implications and Next Steps

The new geochemical and structural evidence markedly expands the exploration potential at Colosseum. Planned next steps include extending surface geochemical sampling coverage along the projected trend of the felsite dykes and developing targets for a maiden drill program outside the pit area. A particular focus will be to test for extensions of the breccia pipe system at depth beneath the newly identified felsite outcrops, as well as to probe adjacent structural zones that mirror the Colosseum ring-dyke pattern.

The Company believes that the Colosseum Project may host additional breccia pipes or related gold-bearing structures that were not recognized during past operations. The combination of a proven high-grade gold system (the defined breccia pipes) and now the identification of geochemical halos extending outward provides a clear roadmap for exploration that could add substantial mineral resources to the project.

The inclusion of rare earth elements in the exploration mix adds a strategically important dimension to the Colosseum Project. REEs are critical minerals used in clean energy, electronics, and defence technologies. Importantly, the existence of a viable gold system at Colosseum provides a strong foundation to pursue REE exploration with greater confidence. The established gold mineral resource and its development potential give

the Company more financial flexibility and technical assurance as it broadens its exploration focus, ensuring that gold and rare earth targets can be advanced in parallel to maximize the project's overall potential.

Dateline Resources will continue to keep shareholders informed as these exploration plans are incorporated into the objectives being developed for the REE exploration program.

This announcement has been authorised for release on ASX by the Company's Board of Directors.

### **About Dateline Resources Limited**

Dateline Resources Limited (ASX: DTR, OTC: DTREF) is an Australian company focused on mining and exploration in North America. The Company owns 100% of the Colosseum Gold-REE Project in California.

The Colosseum Gold Mine is located in the Walker Lane Trend in East San Bernardino County, California. On 6 June 2024, the Company announced to the ASX that the Colosseum Gold mine has a JORC-2012 compliant Mineral Resource estimate of 27.1Mt @ 1.26g/t Au for 1.1Moz. Of the total Mineral Resource, 455koz @ 1.47/t Au (41%) are classified as Measured, 281koz @ 1.21g/t Au (26%) as Indicated and 364koz @ 1.10g/t Au (33%) as Inferred.

On 23 May 2025, Dateline announced that updated economics for the Colosseum Gold Project generated an NPV<sub>6.5</sub> of US\$550 million and an IRR of 61% using a gold price of US\$2,900/oz.

The Colosseum is located less than 10km north of the Mountain Rare Earth mine. Planning has commenced on drill testing the REE potential at Colosseum.

### **Forward-Looking Statements**

This announcement may contain "forward-looking statements" concerning Dateline Resources that are subject to risks and uncertainties. Generally, the words "will", "may", "should", "continue", "believes", "expects", "intends", "anticipates" or similar expressions identify forward-looking statements. These forward-looking statements involve risks and uncertainties that could cause actual results to differ materially from those expressed in the forward-looking statements. Many of these risks and uncertainties relate to factors that are beyond Dateline Resources' ability to control or estimate precisely, such as future market conditions, changes in regulatory environment and the behaviour of other market participants. Dateline Resources cannot give any assurance that such forward-looking statements will prove to have been correct. The reader is cautioned not to place undue reliance on these forward-looking statements. Dateline Resources assumes no obligation and does not undertake any obligation to update or revise publicly any of the forward-looking statements set out herein, whether as a result of new information, future events or otherwise, except to the extent legally required.

## Competent Person Statement

Sample preparation and any exploration information in this announcement is based upon work reviewed by Mr Greg Hall who is a Chartered Professional of the Australasian Institute of Mining and Metallurgy (CP-IMM). Mr Hall has sufficient experience that is relevant to the style of mineralization and type of deposit under consideration and to the activity which he is undertaking to qualify as a Competent Person as defined in the 2012 Edition of the "Australasian Code for Reporting Exploration Results, Mineral Resources and Ore Reserves" (JORC Code). Mr Hall is a Non-Executive Director of Dateline Resources Limited and consents to the inclusion in the report of the matters based on this information in the form and context in which it appears.
