

29 June 2026

KEY POINTS

- **Lunnon Metals Ltd Board approves \$13 million exploration budget for FY2027**
- **Expanded program to evaluate the gold prospectivity of Lunnon Metals' tenure at St Ives**
- **Aiming to complete over 43km of drilling**
- **Represents the most metres drilled in a single year in FBA's 60-year history**

Lunnon Metals Limited (ASX: LM8) (the **Company** or **Lunnon Metals**) is pleased to provide an update on the Company's discovery program, funding and objectives for FY2027 at the Company's Foster-Baker gold project (**FBA**), located in the middle of the highly prospective St Ives gold camp.

FY2027 Exploration Budget

Based on the continued successful open pit mining at the Company's first gold discovery, Lady Herial, the Company estimates a closing cash balance at 30 June 2026 of approximately \$21.0 million, and is now debt-free, given the recent repayment of the \$6.0 million working capital facility¹.

With the free cash flow forecast to accrue through to the end of open pit mining at Lady Herial in the September 2026 quarter, the Board of Lunnon Metals has approved a FY2027 exploration budget committing \$13.0 million to the FBA. This budget is the first part of a two-year program to fully evaluate the gold potential of the FBA, an area that has been significantly under-explored for gold due to the area's historical focus on nickel.

FBA Exploration Target

The FBA is a coherent geological package that is contiguous with, and was subject to the same Archaean-aged gold mineralisation event as, the broader St Ives gold camp it is hosted within. The FBA plays host to prospects/targets at differing stages of exploration maturity ranging from conceptual through to resource definition (see **Figure 1**). To assist in planning and prioritising the Company's FY2027 exploration activities, the Company's Exploration & Geology Manager (and principal Competent Person) has estimated an Exploration Target covering the FBA.

Accordingly, a project-wide Exploration Target of between approximately 25-30 million tonnes for a potential gold content of between 1.2-2.4 million ounces is reported for the FBA to a depth of 400m. Grades applicable to the Exploration Target range between 1.5 g/t Au and 2.5 g/t Au. The Company highlights that the Exploration Target, and the potential quantity and grade reported, is conceptual in nature, there has been insufficient exploration to estimate a gold Mineral Resource (other than those Mineral Resources previously reported²), and it is uncertain whether further exploration, regardless of the level of spend, will result in the estimation of any Mineral Resource additional to that already reported.

The Exploration Target is a statement or estimate of the exploration potential and is not an estimate of Mineral Resources or Ore Reserves, nor does it imply that these are achievable.

Commenting on the FY2027 Budget and supporting Exploration Target, **Managing Director, Edmund Ainscough**, said: *"The cash flow from Lady Herial has positioned the Company to back our already successful site exploration team to deliver further Mineral Resource growth and potentially a significant new discovery. Since the Company's IPO we have completed over 140km of drilling, discovered and permitted the Baker nickel deposit and subsequently discovered, permitted and commenced mining gold at Lady Herial. In approving the FY2027 budget, the Board recognises this track record, understands that our tenements sit within the historic and productive St Ives gold camp and supports the team in its goal of delivering further significant exploration success to the benefit of all our stakeholders over the coming years".*

Figure 1: Plan view of the FBA showing the interpreted gold belts hosting the current portfolio of high-quality gold targets, ranging in maturity from Conceptual to Resource Definition.

EXPLORATION TARGET BASIS

The Exploration Target is specific to a defined geological setting, namely the FBA's location within the St Ives gold camp. It is quoted as a range of tonnes, gold content and grades. These ranges are used to reflect the level of uncertainty surrounding the supporting data, the different levels of exploration maturity present across the FBA and to recognise that there has been insufficient exploration to estimate a holistic Mineral Resource for the FBA.

The Exploration Target is based on current knowledge and existing data. As the discovery program unfolds, new data, observations and interpretations may mean that the Exploration Target increases or reduces, and/or that data indicates that significant potential is present in the Company's tenure below 400m.

The Exploration Target is not an estimate of Mineral Resources or Ore Reserves, nor does it imply that these are achievable.

The Exploration Target was estimated in order to provide an assessment of both the potential scale and grade of gold mineralisation intersected in drilling to date and provide guidance on the potential scale and grade of gold mineralisation that may be present in areas yet to be tested.

The Exploration Target is a current estimate of the exploration potential for gold on the Company's Foster-Baker leases in those areas where it holds 100% of the mineral rights³ but constrained to a depth of 400m. The Company has limited its Exploration Target to this depth to be conservative and otherwise to focus discovery efforts on prospects likely to present the best chance of being economically viable, should a discovery be made.

There is significant gold mineralisation present at the St Ives gold camp at depths far greater than 400m, in particular at the St Ives Gold Mining Co. Pty Ltd's (**SIGM** - a wholly owned Gold Fields Ltd subsidiary) Invincible discovery, which extends to over 1,100m⁴, and Westgold Resources Ltd's (**Westgold**) Mineral Resources at Beta Hunt which extend to

³ See the Company's Prospectus for description/explanation of the "Excluded Areas" (as shown on various included figures), which is available online on the Company's website <https://wcsecure.weblink.com.au/pdf/LM8/02384115.pdf>.

⁴ Page 36 of <https://www.goldfields.com/pdf/investors/integrated-annual-reports/2025/gold-fields-mmr-2025-supplement.pdf> as at 31 Dec 2025.

depths in excess of 1,200m⁵. SIGM is generally referred to as Gold Fields hereafter to avoid confusion with St Ives, the gold camp.

The basis for the reporting of the Exploration Target is a combination of:

- The results of historical gold exploration activity completed by Gold Fields and to a lesser extent, WMC Resources Ltd; together with
- The results of gold exploration activity already completed by Lunnon Metals since early 2024, leading to:
 - The discovery and reporting of Mineral Resources⁶ at Lady Herial and Hustler in the Foster Gold Belt; and
 - The discovery and/or interpretation of gold mineralisation at Plentiful, Paringa West, Koombana, Guiding Star and Torquata.

Note: where any reference is made below to past production, remaining Mineral Resources and deposit analogues for gold deposits within the broader St Ives gold camp, while these neighbouring deposits provide geological context, their presence does not imply that mineralisation of similar scale or continuity will be identified within the Company's tenure.

- The historical gold production and remaining Mineral Resources at analogous deposits located on the tenements immediately surrounding⁷ the FBA which together with the FBA occur within the same regional geological setting and are interpreted to have formed during the same Archaean-aged gold mineralising event;
- The subsequent potential for gold mineralisation to be present on the FBA with reference to the structural, lithological and mineralisation setting of the FBA within the St Ives gold camp that has now recorded 18Moz⁸ mined with a further 12Moz⁹ remaining as reported by Gold Fields and Westgold in Mineral Resource/Mineral Reserve (see **Figure 2**);
- The exploration, discovery, Mineral Resource definition and operating mining experience and knowledge of the Company's relevant Competent Persons, which has been accumulated during an approximate and collective 90 years (or more) working at the St Ives gold camp for WMC Resources Ltd, Gold Fields Ltd, ACH Nickel Pty Ltd and Lunnon Metals Ltd.

This is not an estimate of Mineral Resources or Ore Reserves. The Company highlights that the Exploration Target, and the potential quantity and grade reported, is conceptual in nature, there has been insufficient exploration to estimate a gold Mineral Resource other than those Mineral Resources previously reported¹⁰, and it is uncertain whether further exploration, regardless of the level of exploration spend, will result in the estimation of any Mineral Resource additional to that already reported.

The proposed exploration activities and timeframes for completion to test the Exploration Target are contained later in this report.

EXPLORATION TARGET - METHODOLOGY

The Exploration Target does not account for potential geological complexity, possible mining method or metallurgical recovery factors which, with further data collection, could impact the Exploration Target positively or negatively.

The Exploration Target was estimated by assessing the prospects and targets present at the FBA as a whole, reviewing the level and commodity focus of existing exploration data (drilling, geochemistry, geophysics and mapping) and thereby assessing the potential for deposits to be found on the FBA based on similarity of host rock and structural setting with existing gold deposits within the St Ives gold camp.

While the application of analogues based on these neighbouring deposits is supported by, and conforms with the geological setting, referencing them and their presence does not imply that mineralisation of similar scale or continuity will be identified within the Company's tenure and therefore the Exploration Target is conceptual in nature.

The FBA is host to belts defined by different lithology and/or structural settings (see **Figure 1**). Some host rocks are believed to be more favourable for gold mineralisation than others. The belts also differ with regard to being along strike from existing, or proximal to, known gold structures with documented Mineral Resources and/or past production hosted in close proximity outside of the Company's own leases. This means that the range of grade and tonnage mined and/or reported from the various styles of gold deposits located within and adjacent to the FBA with relation to each of the belts, also varies.

These areas also host differing levels of infrastructure related to the 60 years of first nickel, and then later gold, related exploration and mining activity, that in turn has led to different levels of exploration data/maturity due to ease of access. Significant powerlines, haulage roads, pipeline and ancillary services corridors, together with two previously active underground nickel mines and the site of the previous St Ives Gold Plant and tailing storage facilities (1987-2003) materially impeded exploration access resulting in different levels of exploration data, be it prior gold and nickel drilling, surface mapping, geochemical and geophysical surveys (see "Maturity" column in later **Table 2**).

The belts are (see **Figure 1**):

- Clifton-Idough Gold Belt
- Foster Gold Belt
- Paringa Gold Belt
- Lunnon Gold Belt
- Cooe Gold Belt

The principal Competent Person has determined that there is a reasonable basis to estimate a project-wide Exploration Target of between approximately **25-30 million tonnes** for a potential gold content of between **1.2-2.4 million ounces** to a depth of 400m in the context of the setting and location of the FBA within the St Ives gold camp. Grades applicable to the Exploration Target range between **1.5 g/t Au** and **2.5 g/t Au**.

The Exploration Target has been compiled by the relevant Competent Persons, and they take responsibility for the form and context in which the Exploration Target appears. The Competent Persons' Statements are included at the end of this report. The exploration program designed to test the Exploration Target is tailored for each belt and takes into consideration the level of existing exploration data, in particular the density, spacing and depth of past drilling that was completed targeting gold.

The Company notes that the sum of recorded past gold production and the remaining gold Mineral Resource hosted at the St Ives gold camp, owned and reported publicly by Gold Fields and Westgold, now totals approximately 30Moz¹⁶.

The FBA constitutes approximately 23km² and is located within the broader St Ives gold camp which itself has an approximate areal extent, including the FBA, of 30km x 7km (210km²).

LEVEL OF EXPLORATION ACTIVITY ALREADY COMPLETED

Although the FBA area has had a significant quantity of drilling historically, this exploration was largely focused on nickel potential. In turn, this means that the spatial areal extent and depth coverage of that drilling for other minerals, such as gold, is comparatively limited (see **Table 1**).

As a further means of summarising the historical drilling at the FBA, Appendices A, B, C and D to the Independent Technical Assessment Report attached to the Company's June 2021 Prospectus, tabulated the total number of holes, number of holes and number of assays that were significant (i.e. > 1.0% Ni or > 1.0 g/t Au) by area and lease, for all drilling completed before the Company's IPO. All drilling completed by the Company since IPO has been reported.

This lack of drilling at depth, and the focus of that drilling on nickel, forms the basis for the Company's thesis that the FBA is under-explored for gold. This thesis is particularly supported considering the significant increase in understanding of the location of gold (relative to host rock units) and the overall quantum of reported gold mineralisation in recent years, in particular by Gold Fields (at the Athena/Hamlet complex and Invincible discovery) and by Westgold (in regard their discoveries at Beta/Hunt) on the neighbouring tenements within the St Ives gold camp.

Subsequent to the Company's re-focus on gold in early 2024, the majority of its own gold drilling has been centred on Lady Herrial and its immediate surrounds in the Foster Gold Belt, limiting the ability to effectively test the full 23km² of the FBA at the project-wide scale.

Summary statistics for bedrock exploration drilling at the FBA, excluding surficial aircore (**AC**), are shown in **Table 1** and **Figure 3** below.

¹⁶ See page 18 of this report for basis of this total figure.

Ignoring the nickel focused drilling which was spatially restricted due to targeting the komatiite/basalt contact, gold focused drilling has been sporadic, focused on small scale targets and to limited average end of hole (EOH) depths.

Table 1: Surface reverse circulation (RC)/diamond (DD) drilling by commodity and period (1967-present).

Period	GOLD		NICKEL	
	Av. EOH Depth	Total Drilling	Av. EOH Depth	Total Drilling
1967-1976	-	-	168	75,183
1977-1986	207	3,931	314	144,241
1987-1996	71	19,275	351	27,746
1997-2006	134	5,219	735	2,941
2007-2016	183	18,259	-	-
2017-2026	91	36,000	344	52,362
Grand Total	100	82,684	265	302,473

The data in the above table and **Figure 3** excludes shallow AC, open pit and underground grade control drilling, five conceptual WA Government Exploration Incentive Scheme drillholes, and any drilling in the Excluded Areas where the Company does not have the gold rights. The breakdown by commodity and year drilled is shown in **Figure 3** below.

Figure 3: RC/DD drilling on FBA from 1967 to present, by commodity, annotated by significant changes in tenure ownership.

With the discovery of Invincible by Gold Fields in 2012, gold has now been found in each rock unit in the St Ives gold camp as shown in the stratigraphic column (**Figure 4**), which includes a stylised representation of the location of the main gold deposits discovered in each unit, along with the year of that discovery.

The Company believes that the extensive nature of gold mineralisation within all host rocks at the St Ives gold camp supports the Company's assessment of prospectivity and the discovery potential of the Company's FBA project.

Analysis of the historical drilling by year, commodity type, areal and depth extent, coupled with the recent and significant gold discoveries made by other companies with tenement holdings and rights within the St Ives gold camp, reaffirms the Company's view that the FBA is considered significantly under-explored with respect to gold.

This assessment is further supported by the near 100% historical focus for nickel under the ownership of WMC Resources Ltd, and the limited extent of gold focused drilling by Gold Fields after acquisition of the mine in December 2001.

Figure 4: The stratigraphic column for St Ives (gold) and Kambalda (nickel) host rocks. With the discovery of Invincible, gold has been found in every member of the Kalgoorlie Domain present at St Ives (after Cowden and Archibald 1987).

Figure 5 highlights the dramatic drop-off in data/drill density at relatively modest depths. Drilling that does penetrate to depth was typically nickel focused drilling targeting the Kambalda nickel contact (brown dash line on **Figure 5**).

Figures 6 & 7 highlight the limited extent of gold focused drilling whilst the plotting of "maximum gold in hole" (i.e. the highest gold assay value in any one hole) indicates the presence of significant gold mineralisation across the FBA.

Figure 6 also highlights the excellent success rate for Lunnon Metals' own gold focused drilling since the re-focus on gold in early 2024, with anomalous gold recorded at the majority of targets and prospects tested.

For personal use only

Figure 5: Stacked series of plan views of the FBA showing all drilling pierce points (each within a +/-25m depth slice) at -100m, -300m and -500m down – highlighting the dramatic drop off in data/drill density at relatively modest depths. Drilling that does penetrate to these depths is typically nickel focused drilling targeting the Kambalda nickel contact (brown dash).

Figure 6: Plan view of the FBA showing the maximum Au grade (g/t) in all historical and recent RC/DD drillholes. Surface interpretive geology shown as a surround on neighbouring Gold Fields leases.

Figure 7: Plan view of the FBA showing the maximum Au grade (g/t) in all RC/DD drilling completed by Lunnion Metals only since 2021. Surface interpretive geology shown as a surround on neighbouring Gold Fields leases.

PROGRAM TO TEST THE EXPLORATION TARGET ~ SUMMARY

The FY2027 exploration budget approved by the Company's Board, funds the proposed exploration activities and is designed to test the Exploration Target. These funds cover the first 12 months of a planned 2-year program to target, evaluate, define and report on the Mineral Resource potential of the Company's FBA leases within the world-class St Ives gold camp.

The first 12 months of the 2-year program will adopt a three-pronged drilling approach:

1. Assessment of the current portfolio of highest ranked identified targets/prospects by drill testing with RC and DD – ***"what we think we know"***
2. Full field AC in poorly drill tested areas (important tool for 2D geochemical vectoring at surface), and generation of additional targets/anomalies at or near surface ***"what might be staring us in the face!"***
3. Full field framework DD (to enable litho-structural 3D geological modelling to depth) and subsequent generation of additional bedrock targets/anomalies – ***"what we definitely don't yet know!"***

Each element above will be supported by detailed local geophysical surveys as appropriate or warranted.

Table 2: Project-wide Exploration Program to test the Exploration Target – FY2027 (Year 1 of 2)

Gold Belt	Maturity (existing gold metres drilled / Ha)	Exploration Milestone	No. Prospects (to be tested)	Approx. Metres Planned	Max. EOH Depth
FBA aircore	n/a	Conceptual	n/a	10,000	n/a
Clifton-Idough	Very low (11)	Conceptual	7	6,200	500
Foster	Moderate (139)	Conceptual through to resource definition	13	17,500	500
Paringa	Low (37)	Early stage	4	3,500	250
Lunnon	Very Low (25)	Conceptual to early stage	6	5,300	400
Cooee	Low (36)	Early stage	1	900	150
Total			31	43,400	

The majority of target testing is designed as a single pass test only. This means that if any one program is successful, additional drilling will be required to progress that successful target towards estimating a Mineral Resource. Funds, rigs and staffing resources would then be diverted accordingly and the exploration program, and Exploration Target, would be reassessed and re-reported accordingly as appropriate.

Specific Goals

A project wide approach will be executed across all gold belts present at FBA to systematically test the current portfolio of highest ranked targets, from early-stage concepts through to defining Mineral Resources, if possible, by:

- Testing >30 targets with first pass drilling programs (out of almost 50 current identified targets)
- Drilling
 - >20,000m RC
 - >10,000m DD
 - >10,000m AC

To emphasise the magnitude of the FY2027 drilling budget, this total of over 43,000m of combined AC, RC and DD would see Lunnon Metals drilling more metres than any other year in the entire history of exploration at the FBA – be it for nickel or gold.

Excluding the proposed AC drilling, 33,000m is also more metres than any other year, bar two in 1979 and 1980, which were both dominated by multiple, deep, nickel focused DD holes (reference earlier **Table 1** and **Figure 3**) and in regard gold only, the total without AC is once more, greater than any previous year at the FBA over the past 60 years. This highlights the significance of the FY2027 budget and the Company's strong commitment to test the Exploration Target, especially so given while still being a "junior sized" explorer.

Regulatory & Heritage Status

The FBA is located on granted Mining Leases. These licences were recently renewed with the new expiry date being 23 December 2046. Lunnon Metals holds 100% of the rights and title to the FBA, subject to certain select reservations and excluded rights retained by Gold Fields, principally relating to the right to gold in the Excluded Areas (shown as red polygons on **Figure 6**) and the rights to process any future gold ore mined at their nearby Lefroy Gold Plant. The FBA comprises 19 tenements, each approximately 1,500 m by 800 m in area. The tenement numbers are as follows:

M15/1546;	M15/1548;	M15/1549;	M15/1550;	M15/1551;
M15/1553;	M15/1556;	M15/1557;	M15/1559;	M15/1568;
M15/1570;	M15/1571;	M15/1572;	M15/1573;	M15/1575;
M15/1576;	M15/1577;	M15/1590;	M15/1592.	

Lunnon Metals enjoys an excellent relationship with the traditional owners, the Ngadju People at its FBA project. With the close support of the Ngadju and its elders, the significant area that has been impacted by nearly 60 years of historical nickel and gold exploration, definition drilling, open pit and underground mining and current infrastructure (powerlines, pipelines, haulage roads and tracks) has been reviewed and agreed to be defined as Previously Disturbed Areas (**PDA** – shaded white on **Figure 8** below) under the Land Access Deed between the parties. The PDA represent a significant component of the project's area.

In addition, the Ngadju surveyed and cleared for mining the current open pit at Lady Herial. As a result of the fact that Lady Herial was permitted and approved so expeditiously, royalties relating to the ongoing gold production have started to be paid, little more than two years after the first discovery hole was drilled. FY2027 activities are designed to stay within the PDA and surveyed areas however, subject to success, new heritage surveys will be required within the exploration period at some point in the future.

Figure 8: Plan view of the FBA showing the extensive Previously Disturbed Areas (white), and recent Lady Herial / Exploration heritage clearance surveys (blue and yellow).

The portfolio of currently identified targets broken down by stage of exploration maturity and summarising the number of targets to be tested in each associated milestone category, is shown in **Figure 9** below.

Figure 9: The Exploration Milestone System & classification of Lunnon Metals current gold portfolio – prospects/targets must achieve specific outcomes prior to progressing to the next stage of exploration activity.

Milestone Definitions

Anomaly Defined. Quality and areal limits of anomalies, defined by geochemistry, geophysics, mapping and/or drilling are consistent with chosen exploration target analogue and warrant bedrock drill testing with the aim of identifying coherent mineralised structures or volumes if present.

Structure Delineated. Sufficient bedrock intersections of mineralisation along strike and down dip such that the width and/or grade indicative of a mineralised system and its orientation and strike continuity is established, requiring local follow up drilling in order to progress the prospect to Inferred Resource if warranted.

Inferred Resource and upwards: As defined in the Joint Ore Reserves Committee of the Australian Institute of Mining and Metallurgy, Australian Institute of Geoscientists and Minerals Council of Australia (JORC): 2012 Edition of the Australasian Code for Reporting of Exploration Results, Mineral Resources and Ore Reserves.

BELT BY BELT DESCRIPTION OF EXPLORATION PROGRAM TO TEST THE EXPLORATION TARGET

The Company highlights that the Exploration Target, and the potential quantity and grade reported, is conceptual in nature, there has been insufficient exploration to estimate a gold Mineral Resource other than those Mineral Resources previously reported¹⁷, and it is uncertain if further exploration, regardless of the level of exploration spend, will result in the estimation of any Mineral Resource additional to that already reported.

While analogue deposits nearby within the St Ives gold camp provide geological context, referencing them and their presence does not imply that mineralisation of similar scale or continuity will be identified within the Company's tenure.

FBA Generally

Across the FBA, approximately 10,000m of AC drilling year-on-year will be a cornerstone of the program across the FBA designed to deliver an approximate spacing of 40m to 80m x 120m to rapidly assess the near surface potential of poorly drill tested areas project-wide.

Clifton-Idough Belt

The Clifton-Idough Belt is an approximate 5km long zone comprising all rock units of the Archaean Kalgoorlie Group from Lunnon Basalt to Paringa Basalt and through to younger Black Flags Group rocks. The belt is defined by its distinctive structural setting, being dominated by second order splay off, and parallel to, the renowned Boulder-Lefroy Fault Zone which is located to the immediate east of the properties.

Past production¹⁸ from the two Excluded Areas at each end of the belt (**Figures 1,5,6 and 7** show the Excluded Areas as red polygons), where Gold Fields currently retains the gold rights (and immediately outside the FBA boundary), is approximately 60,000oz of gold from over 750,000 tonnes, derived from three shallow pits over approximately 0.75km of combined strike and down to a depth of just 40-50m. Geological observations from the adjacent Excluded Areas, where the Company does not hold gold rights, were considered qualitatively in developing geological interpretations and estimates of the level of gold mineralisation present.

Due to the discovery of Lady Herial in the Foster Gold Belt, and the need to focus resources on that asset to generate the free cash flow to underpin this new aggressive approach, Lunnon Metals to date has not undertaken any gold focused exploration drilling in this belt.

Dominated by early-stage conceptual targets, it presents as the highest priority opportunity to make a significant discovery considering its structural position, the plethora of varied potential host rock units and its past production record over such a limited strike and to limited depths.

Over 6km of drilling in approximately 25 holes will test up to 7 high-ranking, high-risk targets to a maximum depth of 500m.

Foster Gold Belt

The Foster Gold Belt is a 7.0km long stratigraphic belt comprising Defiance Dolerite as its major rock unit along with Kapai Slate, Devon Consols Basalt and other local interflow banded iron sediment units. The gold prospects of the Foster Gold Belt are typically hosted in the Defiance Dolerite, a known favourable host for gold in the immediate vicinity of FBA at the Victory-Defiance gold complex a few kilometres to the north, and slightly further north, at the Neptune and Revenge gold complexes under Lake Lefroy (see **Figure 13**).

This belt has been the focus of the vast majority of Lunnon Metals' activity since the refocus on gold in early 2024, owing mainly to the early discovery of Lady Herial (see **Figure 7**). Almost 700 holes, both RC and DD, and 35km of drilling have been completed on this belt since early 2024, primarily at Lady Herial and Hustler, delivering a Mineral Resource of 1.47Mt at 1.6 g/t Au for over 84,000oz¹⁹. The Lady Herial/Hustler MRE area only covers approximately 0.9km of this 7km long belt, down to an effective depth of approximately 150-200m.

Given the success to date, the Foster Gold Belt will receive over 17km of drilling in over 200 holes, testing 13 prospects ranging from conceptual right up to resource definition drilling on the Lady Herial Stage 2 cutback with maximum depths tested up to 500m.

¹⁷ See ASX announcements dated 12 March 2026 (Hustler) and 27 February 2026 (Lady Herial).

¹⁸ Historical production data from Gold Fields Ltd.

¹⁹ See page 22 for a full breakdown of the Company's gold Mineral Resource and Ore Reserves.

Paringa Gold Belt

The Paringa Gold Belt parallels and lies to the immediate west of the Foster Gold Belt. The dominant rock unit present is the Paringa Basalt which plays host to the Apollo, Hamlet and Athena gold deposits on Gold Fields leases to the immediate south of the FBA (see **Figure 13**). The size of these adjacent gold deposits has previously been reported by Gold Fields as approximately 3.7Moz²⁰.

This area has been the second ranking recipient of gold exploration by the Company since its 2024 refocus on gold. Over 70 holes, both RC and DD, and 10km of drilling have been completed on this belt, primarily at Paringa West and Plentiful (see **Figure 7** and **Figure 10**). Highly encouraging drill intercept results such as 8m @ 5.52 g/t Au, 14m @ 2.62 g/t Au, and 0.5m @ 41.98 g/t Au, along with numerous observations of visible gold in both RC and DD holes have been recorded to date.

Other significant results, in both recent Lunnon Metals' programs but also from historical drilling (2011 vintage and with prefix 'CD') in the vicinity, that are not attributable to either the main Plentiful or 050 Paringa structures, highlight the gold prospectivity of the Paringa Gold Belt in general, with narrow high-grade results at both shallow and slightly deeper depths on as yet unrecognised or yet to be defined structures. Highlights²¹ include (above a 0.5 g/t Au cut-off) 1.0m @ 2.26 g/t Au (PBS26RC_048 from 113m), 1.0m @ 11.05 g/t Au (CD15289 from 70m), 1.0m @ 3.72 g/t Au (CD15291 from 84m), 1.0m @ 10.55 g/t Au (CD15292 from 42m) and 2.0m @ 1.78 g/t Au (CD15293 from 110m).

Figure 10: Plan view of a portion of the Paringa Gold Belt showing maximum gold values in all historical and Company RC/DD holes (coloured spheres), together with the location of EIS Holes #1 and #2 :from recent 7 May 2026 ASX announcement.

Geological modelling and estimation methodologies were applied to the relatively close spaced drilling at the Plentiful and Paringa West prospects within the Paringa Gold Belt but considered only appropriate for assessing conceptual exploration potential rather than Mineral Resource reporting. The limited extent of drilling has demonstrated potentially economic gold mineralisation is present, however the true potential of this belt is as yet undetermined.

²⁰ "Ounces Mined by Mining Area": <https://www.goldfields.com/pdf/investors/shareholder-information/transcripts/2014/australia-site-visits/st-ives-gold-mine.pdf> (p 20).

²¹ See ASX announcements dated 9 January and 7 May 2026.

The immediate Plentiful and Paringa West prospects are incomplete with respect to testing with only localised areas of close space drilling, and gold mineralisation remains open along strike and down dip.

Given the Company's early discovery of gold mineralisation at the Paringa West and Plentiful prospects, the past production and remaining MRE of gold to the immediate south of the FBA on Gold Fields leases in the very same host rocks and belt, and the additional, relatively under-explored nature of this belt in comparison for example to the Foster Gold Belt, the Paringa Gold Belt will receive 3,500 metres of drilling, testing 4 prospects to an approximate maximum depth of 250m, along with a majority share of the FBA wide AC program.

Lunnon Gold Belt

The Lunnon Gold Belt occupies an area to the east of the Foster Gold Belt and below the famous Kambalda nickel contact and is dominated by the extensive Lunnon Basalt. The basalt is in turn terminated to the east by the regionally significant, southwest dipping, Foster Thrust, an early thrust fault that at the FBA superimposes the lower units of the Kalgoorlie Group on top of the younger, higher members such as Defiance Dolerite and Paringa Basalt.

Recalling the historical near 100% focus on nickel sulphide exploration, little to no meaningful drilling has ever occurred on the Lunnon Gold Belt due to its stratigraphic position in the footwall of (i.e. below) the extensive nickel sulphide deposits found throughout the Kambalda-Widgiemooltha district.

The so-called Father's Day Vein discovery²² at nearby Beta Hunt gold/nickel mine (see **Figure 13**), then owned and operated under sub-lease from Gold Fields by TSX listed Karora Resources (previously RNC Minerals and now acquired by Westgold) changed this view. The prospectivity for gold in the Lunnon Basalt, and in particular the regionally extensive Lunnon Sediment (which sits approximately 80-150m below the nickel contact), was now recognised. That discovery in 2018 also highlighted the potential for the Lunnon Sediment to record extreme high-grade gold mineralisation (see **Figure 11**).

Successful extensional exploration by Westgold has now increased the gold hosted in the multiple, parallel stacked quartz lode system within the Lunnon Basalt at Beta/Hunt to over 4.6Moz²³ with any Father's Day Vein style, ultra-high grade specimen stone associated with Lunnon Sediment likely additional to this figure.

Figure 11: Imagery and geological cross sections from RNC Minerals (now part of Westgold) announcements relating to the discovery of the so-called "Father's Day Vein" at Beta Hunt nickel/gold mine in September 2018 within the Lunnon Basalt/Sediment.²⁴

Significantly for Lunnon Metals, the Lunnon Basalt at FBA also hosts the Lunnon Sediment over a strike extent of at least 5.0km and scout drilling reported²⁵ at the end of 2024 intersected broad low grade and narrow very high-grade gold mineralisation thought to represent the Lady Herrial structures interacting with this favourable host (see **Figure 12** and ASX announcement dated 17 December 2024).

²² See ASX announcement dated 22 April 2024, specifically pages 5 & 6 titled "Lunnon Sediment – an Emerging Opportunity".

²³ <https://www.westgold.com.au/gold-operations/mineral-resources-and-ore-reserves> as at 30/6/2025.

²⁴ Imagery sourced from, and reference made to, TSX: RNC announcements dated 9, 16 and 24 September 2018.

²⁵ See ASX announcement dated 17 December 2024.

Note: while these analogue deposits nearby within the St Ives gold camp provide geological context, their presence does not imply that mineralisation of similar scale or continuity will be identified within the Company's tenure.

Figure 12: Plan view of the Lady Herial area showing December 2024 and earlier drill intercepts indicating the prospectivity of the Lunn Sediment to host both broad low grade and narrow high grade gold mineralisation.

Based on the potential for gold mineralisation analogous to the Father's Day Vein discovery at Beta Hunt, and coupled with the potential for more typical St Ives gold camp style quartz-breccia lode gold deposits, the Lunn Gold Belt is seen as a high-priority and will attract over 5km of drilling, testing six key targets with over 40 holes to a maximum depth of 400m.

Cooee Gold Belt

The Cooee Gold Belt parallels and lies between the Foster Gold Belt and the Lunn Gold Belt. The dominant rock unit present is Kambalda Komatiite which plays host to all the nickel sulphide mineralisation across the Kambalda district at, or proximal to, its contact with the underlying Lunn Basalt. Ignoring nickel focused drilling, the Company has completed only limited and sporadic drilling in this belt. The belt was also host to only limited historical workings dating back to the area's prospecting heyday in the 1920s.

Due to the limited drilling and smaller, spatial extent of this belt, limited drilling will occur here in FY2027, with one program of 12 holes testing the Cooee historical workings down to a depth of 150m.

SUMMARY RELEVANT EXTERNAL MINERAL RESOURCE, ORE RESERVE & PAST PRODUCTION FIGURES

See prior Figure 2.

Current SIGM Exclusive Mineral Resources & Mineral Reserves (Gold Fields Ltd)²⁶

Exclusive Measured & Indicated Mineral Resource (excluding Mineral Reserve)

- 16.8Mt @ 2.72 g/t Au (1.467 Moz)

Inferred Mineral Resource

- 14.5Mt @ 4.07 g/t Au (1.897 Moz)

Mineral Reserve

- 38.6Mt @ 3.11 g/t Au (3.854 Moz)

Current Beta Hunt Mineral Resources (Westgold Resources Ltd)²⁷

Measured, Indicated & Inferred Mineral Resource (includes any Ore Reserve reported separately)

- 63.6Mt @ 2.29 g/t Au (4.653 Moz)

Total Past Production – St Ives Gold Camp (Multiple Past and Current Owners)²⁸

- 182.4Mt @ 3.1 g/t Au (18.0 Moz mined)

This announcement has been approved for release by the Board.

²⁸ Sum of historical WMC production records to December 2001, sum of Gold Fields Ltd's, Karora Resources and Westgold Resources report filings thereafter.

BACKGROUND: ST IVES / KAMBALDA - ONE OF AUSTRALIA'S MOST PROLIFIC GOLD CAMPS

The Kambalda / St Ives gold camp is one of Australia's most prolific gold production and discovery centres. Gold has been produced in the area since the discovery of the Red Hill gold mine in 1896 (adjacent to the Company's historical Silver Lake nickel mine at Kambalda). The area immediately encompassing and surrounding the FBA project produced gold from the 1920s onwards, but this goldfield came to prominence in the early 1980s when WMC commenced dedicated gold production from the adjacent Victory-Defiance Complex and the Hunt nickel mine, approximately 15km to the north near Kambalda.

The St Ives Gold Mine was sold by WMC to Gold Fields Limited (**Gold Fields**) in December 2001 after 5.6Moz^{29a} of gold had been produced. With an expanded exploration budget requisite with being one of the world's major gold companies, Gold Fields has gone on to mine over 11Moz^{29b} of gold itself and has found what is shaping to be the most significant discovery in the camp's history, the Invincible deposit (see **Figure 13**), suggesting that the biggest deposits are not always found first in the discovery cycle.

ABOUT THE KAMBALDA GOLD & NICKEL PROJECT (KGNP)

The KGNP features approximately 47sqkm of tenements in the Kambalda/St Ives district. KGNP is located approximately 570km east of Perth and 50-70km south-southeast of Kalgoorlie, in the Eastern Goldfields of Western Australia. KGNP comprises two project areas, Foster and Baker* (19 contiguous mining leases) and Silver Lake and Fisher* (20 contiguous mining leases).

The KGNP is accessed via public roads, well-established mine road infrastructure and the main St Ives causeway over Lake Lefroy. The KGNP is broadly surrounded by tenements held by SIGM, a wholly owned subsidiary of Gold Fields Limited (JSE:GFI) and the Company's major shareholder. The Company holds all mineral rights over the FBA, except gold in specific "Excluded Areas"³⁰ (see earlier **Figure 6 or 7**). High-grade quartz veins were mined by prospectors in the 1920s in what was then called the Cooee/St Ives field (see ASX announcement dated 22 April 2024) with gold ore won from these workings treated at either the nearby historical State Battery or the privately owned Ives Reward battery, the relic sites of which are both located on what are now Lunnon Metals' leases.

The Company highlights that all gold prospects being tested and evaluated are 100% owned by Lunnon Metals. The FBA project is located on granted mining tenements with significant existing infrastructure in place. Nearby gold plants include the Lefroy plant, a few kilometres to the north and owned and operated by the Company's major shareholder Gold Fields, Lakewood (ASX:BC8) and Higginsville plants (ASX:WGX).

*SIGM retains right³⁰ to explore for and mine gold in the "Excluded Areas" at the FBA, as defined in the subsisting agreements between Lunnon Metals and SIGM, and on the remaining area of the tenements, has select rights to gold in limited circumstances.

*The Company has the exclusive rights to nickel on 19 mining leases and related access rights on one additional tenure. Gold Fields retains the rights to the other minerals (except to the extent minerals occur in conjunction with nickel mineralisation or nickel bearing ore but excluding gold).

²⁹ (a) sum of historical WMC production records to Dec 2001 and (b) sum of Gold Fields Annual Report filings thereafter.

³⁰ Refer to the Company's Prospectus (lodged 11 June 2021) for further details. SIGM has a pre-emptive right over gold material from the FBA (other than the Excluded Areas and the Lady Herial deposit).

DISCLAIMER

References in this announcement may have been made to certain previous ASX announcements, which in turn may have included Exploration Results, Exploration Targets, Mineral Resources, Ore Reserves and the results of Scoping and Pre-Feasibility or Feasibility Studies. For full details, please refer to the said announcement on the said date. The Company is not aware of any new information or data that materially affects this information. Other than as specified in this announcement and mentioned announcements, the Company confirms it is not aware of any new information or data that materially affects the information included in the original market announcement(s), and in the case of estimates of Mineral Resources and Ore Reserves (if reported) that all material assumptions and technical parameters underpinning the estimates in the relevant announcement continue to apply and have not materially changed. The Company confirms that the Competent Person's findings in relation to the estimates of Mineral Resources and Ore Reserves (if reported) have not been materially modified from the original announcements reporting those estimates.

Figure 13: Location of the KGNP (red outlines) at the local Kambalda Nickel District / St Ives Gold Camp scale; showing surface geology and structure of this significant Australian gold camp.

COMPETENT PERSONS' STATEMENTS

Any information in this or previous announcements that relates to gold and nickel geology, or informed gold and nickel Mineral Resources, **the Exploration Target reported today**, Exploration Results and the Company's Historical Core Program, which includes the accessing, re-processing, re-logging, cutting and assaying of historical WMC diamond core and the appropriateness of the use of this data and other historical geoscience hard copy data such as cross sections, underground level mapping plans, longitudinal projections and long sections, including commentary relying on personal experience whilst employed at Kambalda by WMC and Gold Fields, is based on, and fairly represents, information and supporting documentation prepared by Mr. Aaron Wehrle, who is a Member of the Australasian Institute of Mining and Metallurgy (**AusIMM**).

Mr. Wehrle is a full-time employee of the Company, a shareholder and holder of employee options/performance rights; he has sufficient experience that is relevant to the style of mineralisation and types of deposit under consideration and to the activity that he is undertaking to qualify as Competent Person as defined in the 2012 Edition of the Australasian Code for Reporting of Exploration Results, Mineral Resources and Ore Reserves (**JORC Code**). Mr. Wehrle is the Company's **principal Competent Person** and consents to the inclusion in this announcement of the matters relating to the **Exploration Target** based on his information in the form and context in which it appears.

Any information in this or previous announcements that relates to, or informed, the Lady Herial or Hustler Mineral Resource estimate, geostatistics, methodology and estimation is based on, and fairly represents, information and supporting documentation prepared by Mr. Stephen Law, who is a Fellow of the AusIMM and also holds current Chartered Professional (Geology) status. Mr Law is a full-time employee of Lunnon Metals Ltd, a shareholder and holds employee performance rights; he has sufficient experience that is relevant to the style of mineralisation and type of deposit under consideration and to the activity that he is undertaking to qualify as Competent Person as defined in the JORC Code. Mr. Law consents to the inclusion in this announcement of the matters based on his information in the form and context in which it appears.

Any information in this or previous announcements that relates to or informed the previous Lady Herial area gold metallurgical testwork program, was based on, and fairly represents, information and supporting documentation prepared by Mr. Barry Cloutt, who is a Member of the AusIMM. Mr. Cloutt is an external and independent consultant to the Company and has sufficient experience that is relevant to the activity that he is undertaking to qualify as Competent Person as defined in the JORC Code. Mr. Cloutt consented to the inclusion in this Study of the matters based on his information in the form and context in which it appears.

Any information in this or previous announcements that relates to the mining, metallurgical and environmental Modifying Factors or assumptions (including information in prior Table 1, sections 1,2,3 and 4), as they may apply was based on, and fairly represents, information and supporting documentation prepared by Mr. Wehrle, Mr. Max Sheppard and Mr. Edmund Ainscough. Messrs. Sheppard and Ainscough are also Competent Persons and Members of the AusIMM. Mr Ainscough is a full-time employee, and Mr Sheppard is a permanent, part-time employee, both of Lunnon Metals Ltd. Both Messrs. Ainscough and Sheppard are shareholders and hold employee performance rights in Lunnon Metals Ltd.

Messrs. Wehrle, Sheppard and Ainscough have sufficient experience that is relevant to the style of mineralisation, both gold and nickel, the types of deposit under consideration, the activity that they are undertaking and the relevant factors, in particular regarding Lady Herial and Hustler specifically and the Foster-Baker project area more generally, the historical Foster mine and the KGNP regionally, to qualify as Competent Persons as defined in the JORC Code. Messrs. Sheppard, Wehrle and Ainscough consent to the inclusion in this announcement of the matters based on their information in the form and context in which it appears.

The information in this announcement or previous announcements that relates to Ore Reserves at Lady Herial is also based on information compiled by Mr. Sheppard, who is a Member of the Australasian Institute of Mining and Metallurgy. Mr. Sheppard's details are as above. Mr. Sheppard has sufficient experience relevant to the style of mineralisation and type of deposit under consideration, and to the activity which he is undertaking to qualify as a Competent Person as defined in the 2012 Edition of the 'Australasian Code for Reporting of Exploration Results, Mineral Resources and Ore Reserves'. Mr Sheppard consents to the inclusion in this report of the matters based on his information in the form and context in which it appears.

GOLD MINERAL RESOURCES

The detailed breakdown, by deposit and mineralised structure, of the Company's gold Mineral Resources³¹, above a 0.5g/t Au cut-off, at 12 March 2026, is as follows:

	Measured			Indicated			Inferred			Total		
	Tonnes	Au g/t	Au Ounces	Tonnes	Au g/t	Au Ounces	Tonnes	Au g/t	Au Ounces	Tonnes	Au g/t	Au Ounces

JORC TABLE 1

The following Table 1 provides the requisite details to the data that contributed to the estimation of the Exploration Target. The following tables address historical WMC and Gold Fields exploration activities/methods and Lunnon Metals' reverse circulation, diamond drilling and aircore programs as well as covering the Company's Historical Core Program, again where relevant. This report may by necessity also then references past DD, RC, AC and grab sampling results, which are therefore covered in this Table 1 for completeness.

SECTION 1: SAMPLING TECHNIQUES AND DATA

Criteria	JORC Code explanation	Commentary
Sampling techniques	<i>Nature and quality of sampling (e.g., cut channels, random chips, or specific specialised industry standard measurement tools appropriate to the minerals under investigation, such as down-hole gamma sondes, or handheld XRF instruments, etc.). These examples should not be taken as limiting the broad meaning of sampling.</i> <i>Include reference to measures taken to ensure sample representivity and the appropriate calibration of any measurement tools or systems used.</i> <i>Aspects of the determination of mineralisation that are Material to the Public Report. In cases where 'industry standard' work has been done this would be relatively simple (e.g. 'reverse circulation drilling was used to obtain 1 m samples from which 3 kg was pulverised to produce a 30 g charge for fire assay'). In other cases, more explanation may be required, such as where there is coarse gold that has inherent sampling problems. Unusual commodities or mineralisation types (e.g. submarine nodules) may warrant disclosure of detailed information.</i>	- All drilling and sampling are undertaken in an industry standard manner both by Lunnon Metals Ltd (Lunnon Metals or the Company) since 2021 and historically by both Gold Fields Ltd (Gold Fields) from 2001 to 2014 and WMC Resources Ltd (WMC) from 1966 to 2001 (collectively Previous Owners). - Lunnon Metals' aircore (AC), diamond drill (DD) and reverse circulation (RC) holes are completed by Blue Spec Drilling Pty Ltd (Blue Spec) following protocols and QAQC procedures aligned with industry best practice. - Any DD holes on the surface of the salt lake, Lake Lefroy, have been drilled to date by Ausdrill Pty Ltd (Ausdrill), using a track-mounted lake rig. RC Lunnon Metals - RC samples are collected directly into calico sample bags on a 1.0m basis from a cone splitter mounted on the drill rig cyclone. 1.0m sample mass typically averages 3.0kg splits. - Sub-sampling techniques and sample preparation are described further below in the relevant section. - Sample sizes are considered appropriate for the material sampled. - The samples are considered representative and appropriate for this type of drilling. - RC samples are appropriate for use in a Mineral Resource estimate. DD Lunnon Metals - Core samples are collected with a DD rig typically drilling HQ (63.5mm core diameter) and/or NQ2 (51mm core diameter) either from surface or as tails from RC pre-collars. Occasionally PQ (83mm core diameter) is drilled in shallow holes which have the additional purpose of collecting material and data for metallurgical and geotechnical studies. HQ3 (61mm core diameter) is occasionally used for shallow geotechnical holes. - All DD core is stored in industry standard plastic core trays labelled with the drill hole ID and core depth intervals. - Sub-sampling techniques and sample preparation are described further below in the relevant section. - Sample sizes are considered appropriate for the material sampled. - The samples are considered representative and appropriate for this type of drilling. - DD core samples are appropriate for use in a Mineral Resource estimate. AC Lunnon Metals - AC samples are collected manually by scoop sampling directly from spoil piles on the ground which have been transferred via plastic buckets from a cyclone mounted on the drill rig. - The field technician collects a single two-metre composite from two consecutive spoil piles starting from the collar, taking care that the resultant composite sample is representative and with a total sample weight of approximately 2.5 ± 0.5 kg. - Each 1.0m spoil mass typically averages $8.5\text{kg} \pm 3.4\text{kg}$. - The final two samples for each hole are sampled on a single metre basis (not composited).

Criteria	JORC Code explanation	Commentary
Sampling techniques (continued)		• Sub-sampling techniques and sample preparation are described further below in the relevant section. • Sample sizes are considered appropriate for the material sampled and the intended use of the assay data in exploration planning only. • AC samples are generally not appropriate for use in a mineral resource estimate. Historical data • Sampling procedures followed by Previous Owners in the drilling, retrieval, and storage of AC, RC and DD samples and core were in line with industry standards at the time. • Surface diamond drill obtaining NQ (48mm) and/or BQ (37mm) diameter drill core, were the standard exploration sample techniques employed by WMC. Underground DD was also used extensively in the operating environment, with drilling of both up and down holes, retrieving typically BQ diameter drill core and to a lesser extent AQ (22mm) diameter drill core. • The core trays were labelled with the drill hole number and numbered with the downhole meterage for the start of the first 1 m run and the end of the last 1 m run on the lip of the core tray and typically included core blocks within the core trays demarcating the depth meterage of rod pull breaks. • The earlier drilling was collected in wooden, and hybrid wooden/steel core trays and occasionally depths recorded in feet. Handheld XRF • Where a handheld XRF tool was used to collect any exploration data reported, it was done so to assess the levels of key chemical elements. The individual XRF results themselves are not reported and any element values or ratios are used as a guide only for lithological and alteration logging/sampling and to assist vectoring to potential mineralisation. No XRF results are used in any MRE. Surface rock chip and grab Sampling • Rock chip samples are taken manually from outcrop exposures using geological pick / crack hammer while grab samples are collected from loose rock material proximal to its original source such as spoils from historical sample pits and surface rock float. • Larger rock samples may be reduced in size using geological pick / crack hammer for representative sample compositing purposes. • Individual samples comprise several rock chips / grab samples from the area of interest, typically totalling 1.0 to 3.0kg collected in pre-numbered calico bags. • The sampling methodology is considered to be appropriate for the intended purpose of the data. • Sub-sampling techniques and sample preparation are described further below in the relevant section. • Sample sizes are considered appropriate for the material sampled and the intended use of the assay data in exploration planning only. • The samples are not considered appropriate for use, and will not be used, in any MRE.
Drilling techniques	<i>Drill type (e.g. core, reverse circulation, open-hole hammer, rotary air blast, auger, Bangka, sonic, etc.) and details (e.g. core diameter, triple or standard tube, depth of diamond tails, face-sampling bit or other type, whether core is oriented and if so, by what method, etc.).</i>	RC Lunnion Metals • RC holes are typically drilled with a 5 1/2-inch bit and face sampling hammer. Holes are drilled dry with use of booster/auxiliary air when/if ground water is encountered. • In the case of short holes not likely to intersect the water table and thus not requiring the use of booster/auxiliary air, a 4-inch bit and face sampling hammer may be used. DD Lunnion Metals • Core samples are collected with a DD rig typically drilling HQ (63.5mm core diameter) and/or NQ2 (51mm core diameter) from surface, or as tails from RC pre-collars, or as wedge holes off parent DD holes. Occasionally PQ (83mm core diameter) or HQ3 (61mm core diameter) is

Criteria	JORC Code explanation	Commentary
Drilling techniques (continued)		drilled in shallow holes which have the additional purpose of collecting material and data for metallurgical and geotechnical studies. • Triple tube HQ or PQ drilling techniques may be used where maximum recovery and preservation of core is required through the weathered zone from surface until competent fresh rock ground conditions are reached. • To help accurately test the targets, "navi" or motor drilling is sometimes used over short runs to control the direction of the drill hole. In these instances, no drill core or sample is returned from that portion of the drill hole. No navi drilling is undertaken within expected intervals of mineralisation. • Wedge holes, where present, utilise the parent hole to a given depth then branch off from the parent hole using either a casing wedge, a Hall-Rowe wedge, or a natural elbow, or navi bend, in the parent hole from where a lip can be cut with the diamond drill bit and the wedge hole drilled straight off the parent. • The DD core is orientated during the drilling process by the drill contractor, using a down hole Reflex ACTIITM Rapid Descent Digital Core Orientation Tool, and then reconstructed over zones of interest by Lunnon Metals field staff for structural and geotechnical logging. AC Lunnon Metals • AC holes are typically drilled with a 90mm outside diameter (25mm inside diameter) open face tungsten carbide bladed drill bit designed to cut through unconsolidated ground formations. The rods used are 75mm outside diameter with a 30mm inside diameter. • Holes are typically drilled dry with use of booster/auxiliary air when/if ground water is encountered. The booster/auxiliary air compressor used has a capacity of 350 psi generating approximately 900 cfm. The compressor is an Atlas Copco compressor. Historical Drilling • Historical surface DD completed by Previous Owners typically comprised HQ, NQ and BQ size drill core. Pre-collars to the surface diamond drillholes are typically PQ and HQ size and occasionally comprised RC drilling techniques. The pre-collars are not typically mineralised. • Underground WMC DD was used extensively in the underground mining environments when present. Drilling included both up hole and downhole, retrieving typically BQ diameter drill core and to a lesser extent AQ diameter drill core. • Although no documentation is available to describe the drilling techniques used by Previous Owners at the time it is understood that the various drilling types used conventional drilling methods consistent with industry standards of the time. • None of the historical WMC diamond drill core was oriented.
Drill sample recovery	<i>Method of recording and assessing core and chip sample recoveries and results assessed.</i> <i>Measures taken to maximise sample recovery and ensure representative nature of the samples.</i> <i>Whether a relationship exists between sample recovery and grade and whether sample bias may have occurred due to preferential loss/gain of fine/coarse material.</i>	For Lunnon Metals AC, RC and DD • Every RC sample is assessed and recorded for recovery and moisture by Lunnon Metals field staff in real time during the drilling process. Samples are monitored for possible contamination during the drilling process by Lunnon Metals geologists. • DD core recovery is measured for each drilling run by the driller and then checked by the Lunnon Metals geological team during the mark up and logging process. • No sample bias is observed. • There is no observed relationship between recovery and gold grade nor bias related to fine or coarse sample material. Historical data • There are no available records for sample recovery for AC, DD or RC drilling completed by Previous Owners; however, re-logging exercises completed by Lunnon Metals of surface and underground DD holes

Criteria	JORC Code explanation	Commentary
		from across the KGNP between 2017 and present found that on average drill recovery was good and acceptable by industry standards.
Logging	<i>Whether core and chip samples have been geologically and geotechnically logged to a level of detail to support appropriate Mineral Resource estimation, mining studies and metallurgical studies</i> <i>Whether logging is qualitative or quantitative in nature. Core (or costean, channel, etc.) photography.</i>	For Lunnon Metals AC, RC and DD (and re-logging of Historical DD where relevant) - Geological logging is undertaken for the entire hole recording lithology, oxidation state, mineralisation, alteration, structural fabrics, and veining, subject to the following exception. - DD orientated structural logging, core recovery, and Rock Quality Designation (RQDs) are all recorded from drill core over intervals of interest and relevance. - Detailed geotechnical logging and rock property test work is completed over intervals of relevance by independent MineGeoTech Pty Ltd (MGT) contractor geotechnical engineers. - Geological logging (and where required, geotechnical logging) is completed in sufficient detail to support future Mineral Resource estimation, mining and metallurgical studies. - Metallurgical test work in the broader project area is ongoing in addition to the geological logging and element assaying detailed below. - General logging data captured are qualitative (descriptions of the various geological features and units) and quantitative (numbers representing structural attitudes, and vein and sulphide percentages, magnetic susceptibility and conductivity). - DD core is photographed in both dry and wet form. - AC and RC chip trays are photographed in both dry and wet form. Historical data - There is no available documentation describing the logging procedures employed by Previous Owners' geologists in the KGNP area. - However, the WMC historical graphical hardcopy logs and other geoscientific records available for the project are of high quality and contain significant detail with logging intervals down to as narrow as 0.01 m. - The geological logs document lithology, textures, structures, alteration, and mineralisation observed in drill core captured both graphically and in a five-character logging code (Lunnon Metals notes that a previous logging legend employed at WMC's Kambalda Nickel Operations utilised a 3-letter code which is often represented on hard copy plans and cross sections of an older vintage and which was converted by WMC to the latter 5-character code at some later time). - Stratigraphy is also captured in a three-character logging code. Sample intervals are recorded on the graphical log. These logging legends are well documented in lieu of a recorded procedure and are utilised by Lunnon Metals in current logging practices. - In regard geotechnical logging or procedures, there is no record of any formal relevant procedures or logging and based on personal experience of the Competent Person, such logging was not routinely completed prior to the introduction of Regulation 10:28 in the WA Mine Safety and Inspection Act, requiring the same in approximately 1996. - Based on the personal experience of the relevant Competent Person to this announcement, having worked for WMC in Kambalda between 1996 and 2001, and Gold Fields between 2001 and 2006, it is known that the Previous Owners had a rigorous and regimented system for storing and archiving the graphical logs physically, microfilmed, and drafted on to master cross sections, plans, and long sections. - Starting in the early 2000s under Gold Fields ownership drillhole logging information was captured digitally via rugged tablet, field- based laptops (known as "Toughbooks") using a newly developed in-house (and industry standard) geological logging legend which was overseen by the Competent Person who was Exploration Manager for the St Ives Gold Mining Co Pty Ltd (SIGM) at that time.

Criteria	JORC Code explanation	Commentary
Logging (continued)		- Both the graphically captured interval data and the more recently digitally captured geological logging information was stored in a secure digital database. - Lunnon Metals sourced historical diamond core from the SIGM Kambalda core yard on Durkin Road where relevant to its investigations. Optical Televiewer downhole surveys - For additional information regarding Optical Televiewer surveys please refer to Table 1 section 2 'Other substantive exploration data' criteria. Surface rock chip and grab sampling - All rock chip / grab samples have been geologically described and recorded by a qualified geologist. - The geological logging was to a level appropriate for exploration planning purposes. - Geological logging of the samples is qualitative in nature.
Sub-sampling techniques and sample preparation	<i>If core, whether cut or sawn and whether quarter, half or all core taken.</i> <i>If non-core, whether riffled, tube sampled, rotary split, etc. and whether sampled wet or dry.</i> <i>For all sample types, the nature, quality and appropriateness of the sample preparation technique.</i> <i>Quality control procedures adopted for all sub-sampling stages to maximise representivity of samples.</i> <i>Measures taken to ensure that the sampling is representative of the in-situ material collected, including for instance results for field duplicate/second half sampling.</i> <i>Whether sample sizes are appropriate to the grain size of the material being sampled.</i>	Lunnon Metals RC - Dry RC samples are collected directly into calico sample bags on a 1.0m basis from a cone splitter mounted on the drill rig cyclone. 1.0m sample mass typically averages 3.0kg splits. - Duplicate samples are collected directly from the drill rig cyclone, at a rate of 1 in every 25 samples and more frequently in the expected mineralised zones. - After receipt of the RC samples by the independent laboratory the samples submitted for fire assay or multielement analysis are typically dried and pulverised with >85% pulverised to 75micron or better. For sample weights > 3kg the sample is dried, split and pulverised up to 3kg. - RC samples submitted for Chryso PhotonAssay™ (PhotonAssay) method of gold analysis, are dried and crushed to ~2-3mm and loaded into 330mL plastic jars (typically 400-650g) ready for analysing. Lunnon Metals DD (and re-sampling of Historical DD where relevant) - DD core samples are most typically collected with a diamond drill rig drilling HQ and/or NQ2 size core. After logging, sample interval mark-up, photographing, and geotechnical rock property test work, selected sample intervals of drill core are cut in half along the length of the drill core with a diamond saw in a Discoverer® Automatic Core Cutting Facility using a Corewise Auto Core Saw. - Typically, one half of the drill core is sent to the laboratory for assay and the other half retained in its original core tray. - The PQ metallurgical holes had one quarter sent to the assay laboratory and the remaining three-quarters is saved for metallurgical testwork samples. - Holes are marked up and sampled for assaying over mineralised and surrounding intervals at a typical minimum sample interval of 0.3m to ensure adequate sample weight and a typical maximum sample interval of 1.0m, constrained by geological boundaries. - Specific Gravity – Sufficient density measurements are taken for each mineralised DD sample for the Lunnon Metals drill holes. - Sample weights vary depending on core diameter, sample length and density of the rock. Regolith zonation is taken into account. - Field duplicate samples are collected at a rate of 1 in 25 samples, and more frequently in the identified mineralised zones, by cutting the core into quarters and submitting both quarters to the laboratory for analysis as two separate samples. - In the case of the metallurgical holes no field duplicates are collected to preserve a consistent amount of core for metallurgical testwork. - After receipt of the DD core samples by the independent laboratory the samples are dried, crushed to ~2mm, and pulverised with >85% pulverised to 75micron or better. For sample weights >3kg the sample is dried, crushed to ~2mm, split, and pulverised up to 3kg.

Criteria	JORC Code explanation	Commentary
Sub-sampling techniques and sample preparation (continued)		• DD core samples submitted for PhotonAssay method of gold analysis, are dried and crushed to ~2-3mm and loaded into 330mL plastic jars (typically 400-650g) ready for analysing. • Sample sizes are considered appropriate for the style of mineralisation. • Samples are submitted to Intertek Genalysis in Kalgoorlie for sample preparation i.e. drying, crushing where necessary, and pulverising. Pulverised samples are then transported to Intertek Genalysis in Perth for analysis. Lunnon Metals AC • AC samples are collected manually by scoop sampling directly from spoil piles on the ground which have been transferred via plastic buckets from a cyclone mounted on the drill rig. • The field technician collects a single two-metre composite from two consecutive spoil piles starting from the collar, taking care that the resultant composite sample is representative and with a total sample weight of approximately 2.5 ± 0.5 kg. • Each 1.0m spoil mass typically averages $8.5\text{kg} \pm 3.4\text{kg}$. • The final two samples for each hole are sampled on a single metre basis (not composited). • Duplicate samples are collected by scoop sampling from the spoils piles into calico sample bags, at a rate of 1 in every 25 samples and more frequently in the expected mineralised zones. Additional field duplicate samples are collected if required from key geological horizons. • After receipt of the AC samples by the independent laboratory the samples are typically dried, crushed to ~2mm, and pulverised with >85% pulverised to 75micron or better. For sample weights >3kg the sample is dried, crushed to ~2mm, split, and pulverised up to 3kg. • AC samples submitted for Chrysos PhotonAssay™ (PhotonAssay) method of gold analysis are dried and crushed to ~2-3mm and loaded into 330mL plastic jars (typically 400-650g) ready for analysing. • Selected AC samples are analysed for a multi-element suite typically comprising 48 elements. Analytical techniques used a four-acid digest (with ICP-OES or ICP-MS finish) of hydrofluoric, nitric, perchloric and hydrochloric acids, suitable for near total dissolution of almost all mineral species including silica-based samples. • Samples are submitted to Intertek Genalysis in Kalgoorlie for sample preparation and then transported to Intertek Genalysis in Perth for analysis. Historical data • All historical core that was relevant to the mineralisation drilled and sampled by WMC as sighted by Lunnon Metals was sawn with half or quarter core sampling practices. It is assumed that all samples otherwise contributing to any estimation of mineralisation by Lunnon Metals were processed with this standard methodology. • In regard historical core if used in a future MRE, subsampling techniques for WMC drilled NQ and BQ and occasionally AQ size drill holes typically involved half and quarter sawn drill core with the quarter core dispatched for assaying in the case of NQ and BQ, and half core in the case of AQ. • Portions of drill core distal to the main high-grade mineralisation were sometimes 'chip sampled' by WMC. Lunnon Metals has chosen not to utilise such samples in any estimation of grade or mineralisation. • WMC typically sampled in interval lengths relevant to the underlying lithology and mineralisation such that sample interval lengths may vary from between minima of 0.05m and maxima up to 2.00m approximately within any mineralised zone. • Intervals of no mineralisation or interest were typically not sampled. • Review of historical drill core by Lunnon Metals indicated that the sample sizes were appropriate for the type, style and thickness of mineralisation being tested with sample breaks corresponding to

Criteria	JORC Code explanation	Commentary
Sub-sampling techniques and sample preparation (continued)		lithological or mineralisation breaks being the norm. Although faded through time, sample depth intervals are evident as marked on the remaining half core as observed by Lunnon Metals and these correlate to sample interval depths in the original paper graphical drill logs and the historical database. • While the Previous Owners' procedures for logging, sampling, assaying and QAQC of drillhole programs was not available at the time of this announcement it is interpreted that it was of high quality and in line with industry standards at that time. • It is the opinion of the relevant Competent Person that the sample preparation, security, and analytical procedures pertaining to the above-mentioned historical drilling by Previous Owners were adequate and fit for purpose based on: - Both WMC and Gold Fields' reputation in geoscience, in WMC's case stemming from their discovery of nickel sulphides in Kambalda in the late 1960s; - identification of procedures entitled "WMC QAQC Practices for Sampling and Analysis, Version 2 – adapted for St Ives Gold" dated February 2001 and which includes practices for gold and nickel; and - the first-hand knowledge and experience of the Competent Person of this announcement whilst working for WMC and Gold Fields at Kambalda between 1996 and 2006. Surface rock chip and grab sampling • As the rock chip / grab samples are intended for exploration planning purposes only no Company sample preparation QAQC processes were undertaken (insertion of CRM's or blanks). Laboratory QAQC protocols were utilized in the sample preparation and analysis phase. • After receipt of the rock chip / grab samples by the independent laboratory the samples are dried, crushed to ~2mm, and pulverised with >85% pulverised to 75micron or better. For sample weights >3kg the sample is dried, crushed to ~2mm, split, and pulverised up to 3kg. • Rock chip / grab samples submitted for PhotonAssay method of gold analysis, are dried and crushed to ~2-3mm and loaded into 330mL plastic jars (typically 400-650g) ready for analysing. • Samples are submitted to Intertek Genalysis in Kalgoorlie for sample preparation i.e. drying, crushing where necessary, and pulverising. Pulverised samples are then transported to Intertek Genalysis in Perth for analysis.
Quality of assay data and laboratory tests	<i>The nature, quality and appropriateness of the assaying and laboratory procedures used and whether the technique is considered partial or total.</i> <i>For geophysical tools, spectrometers, handheld XRF instruments, etc., the parameters used in determining the analysis including instrument make and model, reading times, calibrations factors applied and their derivation, etc.</i> <i>Nature of quality control procedures adopted (e.g. standards, blanks, duplicates, external laboratory checks) and</i>	For Lunnon Metals AC, RC and DD (and re-assaying of Historical DD where relevant) and surface rock chip / grab samples • Samples are submitted to Intertek Genalysis in Kalgoorlie for sample preparation such as drying, crushing where necessary, and pulverising. • Prepared samples are then transported to Intertek Genalysis in Perth for analysis. • For the purpose of gold exploration, samples have been typically submitted for 50g charge lead collection fire assay, while samples specifically located in weathered regolith and mineralised zones are submitted for the same multi-element suite as above for the purpose of assessing potential gold path finder elements. • From 2024 the Company has moved to PhotonAssay™ as its preferred methods of gold analysis. PhotonAssay is a high-energy X-ray source that is used to irradiate large mineral samples, typically about 0.5 kg. The X-rays induce short-lived changes in the structure of any gold nuclei present. As the excited gold nuclei return to their ground state, they emit a characteristic gamma-ray signature, the intensity of which is directly proportional to the concentration of gold. The penetrating nature of PhotonAssay provides much higher energy than those used in conventional X-ray fluorescence (XRF), which provides a true bulk

Criteria	JORC Code explanation	Commentary
	<i>whether acceptable levels of accuracy (i.e. lack of bias) and precision have been established.</i>	analysis of the entire sample. Samples are presented into a fully automatic process where samples are irradiated, measured, data collected and reported. • Samples are analysed for a multi-element suite (typically 33 or 48 elements) including, as a minimum, Ni, Cu, Co, Cr, As, Fe, Mg, Pb, S, Ti, Zn. Analytical techniques used a four-acid digest (with ICP-OES or ICP-MS finish) of hydrofluoric, nitric, perchloric and hydrochloric acids, suitable for near total dissolution of almost all mineral species including silica-based samples. • Within the regolith portion of selected holes, the Triple Quad 53 Element Aqua Regia ICP-MS method may be used. • Within selected gold mineralised zones and all nickel mineralised zones, the platinum group elements (Pd, Pt, Au) are also analysed using a 50g charge lead collection fire assay method with ICP-MS finish. • These techniques are considered quantitative in nature. • Industry prepared certified reference material (CRM), or standard samples, of various grades appropriate to the mineralisation expected are inserted into the sample batches, approximately every 50 samples and more frequently in the expected mineralised zones. • Lunnon Metals prepared blank samples are inserted, approximately every 50 samples and more frequently in the identified mineralised zones. At present blank samples are prepared from CRM Bunbury Basalt. In the past blanks were prepared from barren non-ultramafic RC chips as verified by laboratory analysis or barren non-ultramafic Proterozoic Dyke DD core acquired locally and verified by geological logging. • The independent laboratory also carries out numerous internal standards in individual batches. • The resultant Lunnon Metals and laboratory QAQC data is reviewed upon receipt to determine that the accuracy and precision of the data has been identified as acceptable prior to being cleared for upload to the project-wide Lunnon Metals KGNP Geobank® (Micromine) database (Database). Historical data • There is no data available at the time of this announcement pertaining to the assaying and laboratory procedures nor the historical field or laboratory quality assurance and quality control (QAQC), if any, undertaken by Previous Owners' drilling programs in the KGNP area; however, it is expected that industry standards as a minimum were likely to have been adopted in the KGNP area and the analytical laboratory.
Verification of sampling and assaying	<i>The verification of significant intersections by either independent or alternative company personnel.</i> <i>The use of twinned holes.</i> <i>Documentation of primary data, data entry procedures, data verification, data storage (physical and electronic) protocols.</i> <i>Discuss any adjustment to assay data.</i>	For Lunnon Metals AC, RC and DD • In the case of current gold exploration, previous lodgements have specifically documented the results of drilling DD holes adjacent to previous Company RC holes. • Specific assayed gold interval samples nominated for verification are either re-split in the field via riffle splitter in the case of RC samples, or in the case of DD core the remaining half of core from the core trays are sampled. These full intervals of duplicate samples are assayed via the original and/or alternative methods as a means of verifying the original gold assays. • Prior to drilling, all planned collar data is captured in a digital drillhole collar register stored on a secure site-based server which is backed up to Perth based server continuously. The collar register is updated as drilling progresses and is completed. • Sample intervals are captured in digital QAQC'd spreadsheets via Toughbooks. • Since September 2023 the data collected on the Toughbooks synchronises directly to the Database stored on a separate secure sequel server. A set of buffer tables store the data before the database administrator does a second validation of the data (driven by in-built

Criteria	JORC Code explanation	Commentary
Verification of sampling and assaying (continued)		validation rules in the Database) before loading to the production data tables. - Assays from the laboratory are sent directly to the database administrator via a dedicated Lunnon Metals assays email address where they are all checked and verified by the Lunnon Metals database administrator before accepting the batches into the database. - No adjustments are made to the original assay data. Only the Lunnon Metals database administrator has editable access to assay values stored in the Database and an internal periodic audit protocol is in place to verify Database assay values against original laboratory provided assay data. Historical data - Diamond core data – across the KGNP, Lunnon Metals has undertaken exhaustive assessment of historical WMC underground and surface diamond drill core to inspect and visually validate significant drill assays and intercepts, and re-sample and re-assay to validate historical assay data in the KGNP Database. - No significant or systematic inconsistencies have been identified, and the Competent Person is satisfied that the original data in the project area is representative of the geology and mineralisation modelled; thus, no adjustments to assay data have been deemed necessary or made. Surface rock chip and grab sampling - No verification of sampling and assaying of surface rock chip/grab samples is undertaken. No rock chip data is used in any MRE.
Location of data points	<i>Accuracy and quality of surveys used to locate drillholes (collar and down-hole surveys), trenches, mine workings and other locations used in Mineral Resource estimation.</i> <i>Specification of the grid system used.</i> <i>Quality and adequacy of topographic control.</i>	General - The grid projection is GDA94/ MGA Zone 51. - Diagrams and location data tables have been provided in the previous reporting of exploration results where relevant. For Lunnon Metals AC, RC and DD - RC and DD hole collar locations are located initially by handheld GPS to an accuracy of +/- 3m. Planned resource drill holes are set out by a licensed surveyor for better than 3m accuracy. Subsequently, drill hole collar locations are then picked up by a licensed surveyor using DGPS methods following the completion of the drilling. - All drill holes are typically surveyed downhole at 5m intervals using the REFLEX gyro Sprint-IQ (north seeking gyro) system for both azimuth and dip measurements or the new REFLEX gyro OMNIx42, which is stated to have an even greater accuracy than the Sprint-IQ. - Downhole surveys are uploaded by Blue Spec and Ausdrill to the IMDEXHUB-IQ, a cloud-based data management program where surveys are validated and approved by trained Lunnon Metals staff. Surveys can now be validated live and in 3D with the introduction of Seequent Central to the process, a cloud-based management system with direct integration between IMDEX and Leapfrog Geo (3D geology modelling software). Approved exports are then downloaded to the server and after additional QAQC checks and sign off the survey data is uploaded to the Database. The input file is the same file directly downloaded from the IMDEX hub, so data entry errors are eliminated. Historical data - Historical methods of drill collar survey pick-up are not recorded however Previous Owners did employ surface surveyors dedicated to the collection of exploration collar data. The easting, northing and elevation values were originally recorded in local KNO ('Kambalda Nickel Operations') grid and later converted to the currently used GDA94/MGA Zone 51 grid. Both the original KNO grid coordinates and the converted coordinates are recorded in the Database. A representative number of historical drill collars were located in the field and their locations cross checked via differential GPS and/or handheld GPS to validate the Database collar coordinates.

Criteria	JORC Code explanation	Commentary
Location of data points (continued)		- Historical hardcopy downhole survey data is generally available for the majority of surface drillholes, and the records show that single shot magnetic instruments were used. A representative number of these hardcopy downhole survey records have been cross checked against the digital records in the Database. - Downhole surveys of select historical surface DD have been conducted using modern gyro systems as described above and no significant errors or inconsistencies were deemed present. - Lunnon Metals has corrected where necessary incorrect data in the Database where down hole measurements from the hardcopy data were incorrectly processed. - No other significant errors or inconsistencies were deemed present or capable of being detrimental to any interpretation of gold or nickel mineralisation, including any MRE work. Surface rock chip and grab sampling - The rock chip / grab sampling points are located by handheld GPS to a typical accuracy of +/- 3m.
Data spacing and distribution	<i>Data spacing for reporting of Exploration Results.</i> <i>Whether the drill spacing and distribution is sufficient to establish the degree of geological and grade continuity appropriate for the Mineral Resource and Ore Reserve estimation procedure(s) and classifications applied</i> <i>Whether sample compositing has been applied</i>	For Lunnon Metals AC, RC and DD - The AC, RC and DD programs at KGNP comprise drillhole spacings that are dependent on the expected target style and size, orientation and depth. Drillholes are not necessarily drilled to set patterns or spacing at the exploration stage of the program. - Previous drill spacing varies greatly, again subject to the target style, dimensions, orientation and depth and inherent geological variability and complexity. - All holes have been geologically logged and provide a strong basis for geological control and continuity of mineralisation. - No sample compositing has been applied other than to AC drilling where typically a single sample composite is produced from 2 individual metres of drilling however AC results are not appropriate for use, and have not been used, in any mineral resource estimate. - Assay results for all drill types are composited at the reporting stage of drill intercepts within a single hole. - In the case of drilling intended to serve as grade control on which future open pit production could be designed and scheduled, such as is the case at the Lady Herial gold deposit, the drill spacing aims to approximate 8m x 6m to 10m x 10m depending on the scale and variability of the mineralisation being defined. Historical data - The typical spacing for the early WMC DD surface drill traverses varies but is typically approximately 200m to 400m apart with drillhole spacing along the traverses at 100m to 50m. In areas of shallower RC drilling this drill spacing is sometimes improved to 100m by 50m or even 50m by 50m. - The drill spacing for areas the subject of underground DD holes was variable but was on average spaced at approximately 20m along the strike of a mineralised zone with fans or rings of DD holes that deliver pierce points in the dip orientation at variable spacing, but typically 10m to 20m apart. - The drill spacing for the gold prospects reported, with both Lunnon Metals surface DD and RC and Previous Owners surface DD, RC and AC, is variable but ranges typically from 320m, 160m, 80m, 40m, to 20m hole spacing depending on the maturity or state of advancement of the prospect by those Previous owners. Surface rock chip and grab sampling - Not relevant to the reporting of rock chip / grab samples. - Spacing of sample location is arbitrary, and dependent on the surface exposures identified in the field.

Criteria	JORC Code explanation	Commentary
Data spacing and distribution (continued)		The location, assay results and geological descriptions of the rock chip / grab samples reported is not appropriate for use, and will not be used, in any mineral resource estimate.
Orientation of data in relation to geological structure	<i>Whether the orientation of sampling achieves unbiased sampling of possible structures and the extent to which this is known, considering the deposit type.</i> <i>If the relationship between the drilling orientation and the orientation of key mineralised structures is considered to have introduced a sampling bias, this should be assessed and reported if material.</i>	- The preferred orientation of drilling at KGNP is designed to intercept the target approximately perpendicular to the strike and dip of the mineralisation where/if known. Subsequent sampling is therefore considered representative of the mineralised zones if/when intersected. - The chance of bias introduced by sample orientation relative to structures, mineralised zones or shears at a low angle to the drillhole is possible, however quantified orientation of the intercepted interval allows this possible bias to be assessed. Where drilling intercepts the interpreted mineralisation as planned, bias is considered non-existent to minimal. - Lunnon Metals does not consider that any bias was introduced by the orientation of sampling resulting from any particular drilling technique. - Where drilling intercepts the interpreted mineralisation as planned, bias is considered non-existent to minimal.
Sample security	<i>The measures taken to ensure sample security.</i>	Lunnon Metals RC and AC - The calico sample bags are collected by Lunnon Metals personnel stationed at the drill rig typically at the end of each day. The calico samples are collected sequentially in groups of five and placed into polyweave bags, or more recently green plastic bags, which are labelled and secured with cable ties. The polyweave bags are in turn placed in bulka bags which are secured on wooden pallets and transported directly via road freight to the laboratory with a corresponding submission form and consignment note. - The laboratory checks the samples received against the submission form and notifies the Company of any inconsistencies. Once the laboratory has completed the assaying, the pulp packets, pulp residues and coarse rejects are held in the Laboratory's secure warehouse until collected by the Company or approves them to be discarded. Lunnon Metals DD (and re-sampled Historical DD where relevant) - After the drill core is cut and returned to its original position in the core tray, Lunnon Metals' geologists mark up the drill core for sampling and records the sample intervals against unique sample numbers in a digital sample register. - A Lunnon Metals core farm technician then collects the cut core samples into calico bags guided by the sample register and sampling information contained therein. - The calico samples are collected sequentially in groups of five and placed into polyweave bags which are labelled and secured with cable ties. The polyweave bags are in turn placed in bulka bags which are secured on wooden pallets and transported directly via road freight to the laboratory with a corresponding submission form and consignment note. - The laboratory checks the samples received against the submission form and notifies Lunnon Metals of any inconsistencies. Once the laboratory has completed the assaying, the pulp packets, pulp residues and coarse rejects are held in the laboratory's secure warehouse until collected by Lunnon Metals or approval is provided for them to be discarded. Historical data - There is no documentation which describes the historical sample handling and submission protocols during Previous Owners' drilling programs; however, it is assumed that due care was taken with security of samples during field collection, transport and laboratory analysis. The historical drill core remaining after sampling was stored and catalogued at the KNO core farm (now Gold Fields, SIGM core farm) and it remains at this location to the present day.

For personal use only

Criteria	JORC Code explanation	Commentary
Audits or review	<i>The results of any audits or reviews of sampling techniques and data.</i>	• No external audits or reviews have been undertaken at this stage of the program. WMC Historical data • Cube Consulting Pty Ltd (Cube) are independent of Lunnon Metals and have been previously retained by Lunnon Metals to complete the grade estimation for nickel mineralisation models and MRE exercises. • Cube were also requested to review and comment on the protocols developed by Lunnon Metals to deal with, and thereafter utilise, the historical WMC Resources' data, in particular the re-sampling and QAQC exercise completed by Lunnon Metals such that the data is capable of being used in accordance with current ASX Listing Rules where applicable and JORC 2012 guidelines and standards for the generation and reporting of MREs. • Cube documented no fatal flaws in that work completed by Lunnon Metals in this regard.

SECTION 2: REPORTING OF EXPLORATION RESULTS

Criteria	JORC Code explanation	Commentary
Mineral tenement and land tenure status	<i>Type, reference name/number, location and ownership including agreements or material issues with third parties such as joint ventures, partnerships, overriding royalties, native title interests, historical sites, wilderness or national park and environmental settings. The security of the tenure held at the time of reporting along with any known impediments to obtaining a licence to operate in the area.</i>	• The property is located on granted Mining Leases. Although all the tenements wholly or partially overlap with areas the subject of determined native title rights and interests, the Company notes that the original grant of the right to mine pre-dates 23 December 1996 and as such section 26D of the Native Title Act may be applied to exempt any future renewals or term extensions from the right to negotiate in Subdivision P of the Act. • Notwithstanding the above, on January 9, 2025, the Company announced that it had executed a Mining Agreement with the Ngadju Native Title Aboriginal Corporation RNTBC (NNTAC), covering the relevant parts of the KGNP that fall on Ndadju Determination Area country. The renewal of the Company's mining licences has now been confirmed with the new expiry date being 23 December 2046. • The complete area of contiguous tenements on which the Silver Lake-Fisher project and rights is located is, together with the wholly owned Foster-Baker project area on the south side of Lake Lefroy, collectively referred to as the Kambalda Gold & Nickel Project ("KGNP") area. • Gold Fields Ltd's wholly owned subsidiary, SIGM, remains the registered holder and the beneficial owner of the Silver Lake- Fisher area. • Lunnon Metals holds: - 100% of the rights and title to the Foster-Baker (FBA) area of KGNP, its assets and leases, subject to certain select reservations and excluded rights retained by SIGM, principally relating to the right to gold in defined areas and the rights to process any future gold ore mined at their nearby Lefroy Gold Plant; - The FBA project area of KGNP comprises 19 tenements, each approximately 1,500 m by 800 m in area, and three tenements on which infrastructure may be placed in the future. The tenement numbers are as follows: M15/1546; M15/1548; M15/1549; M15/1550; M15/1551; M15/1553; M15/1556; M15/1557; M15/1559; M15/1568; M15/1570; M15/1571; M15/1572; M15/1573; M15/1575; M15/1576 M15/1577; M15/1590; M15/1592; - and additional infrastructure tenements: - M15/1668; M15/1669; M15/1670; and - 100% of the mineral rights to nickel and associated metals in the Silver Lake-Fisher (SLF) project area of KGNP, subject to the rights retained by SIGM as tenement holder and as detailed in the Mineral Rights Agreement (MRA). The tenement numbers are as follows (note select tenements are not wholly within the MRA area): M15/1497; M15/1498; M15/1499; M15/1505; M15/1506; M15/1507; M15/1511; M15/1512; M15/1513; M15/1515; M15/1516; M15/1523; M15/1524; M15/1525; M15/1526; M15/1528; M15/1529; M15/1530; M15/1531; and access rights to ML15/0142. • There are no known impediments to potential future development or operations, subject to relevant regulatory approvals, over the leases where significant results have been reported. • The tenements are in good standing with the Western Australian Department of Mines, Petroleum and Exploration

For personal use only

Criteria	JORC Code explanation	Commentary
Exploration done by other parties	<i>Acknowledgement and appraisal of exploration by other parties.</i>	• In relation to nickel mineralisation, WMC, now BHP Nickel West Pty Ltd and a wholly owned subsidiary of BHP Group Ltd, conducted all relevant exploration, resource estimation, development and mining of the mineralisation at Foster, Jan, Silver Lake and Fisher mines from establishment of the mineral licences through to sale of the properties to SIGM in December 2001. Whilst the majority of this prior work had a nickel focus, some gold exploration did occur. • Approximately over 550,000m of DD was undertaken on the properties the subject of the FBA and SLF area by WMC prior to 2001. • SIGM has conducted later, limited gold exploration activities on the KGNP area since 2001, however until nickel focused work recommenced under Lunnon Metals management, no meaningful nickel exploration has been conducted since the time of WMC ownership and only one nickel focused surface diamond core hole (with two wedge holes), was completed in total since WMC ownership and prior to Lunnon Metals' IPO. • In relation to gold exploration, Lunnon Metals adopted a 100% gold focused strategy in early 2024. Since that time over 34km of drilling has been completed by the Company, with over 500 RC holes and 25 DD holes completed. • In relation to past gold production, no modern gold production has occurred on FBA leases where Lunnon Metals has the gold rights. 1920s vintage gold production occurred and is understood to have totalled approximately 50k short tons, for 23.4koz of gold (source: "WA Government List of Cancelled Gold Mining Leases (which have produced gold)" WA DMP 1954). • On the KGNP, past total production from underground mining was conducted by WMC and was solely focused on nickel, recording in contained nickel metal terms: - Foster 61,129 nickel tonnes; - Jan 30,270 nickel tonnes; - Fisher 38,070 nickel tonnes; and - Silver Lake 123,318 nickel tonnes.
Geology	<i>Deposit type, geological setting and style of mineralisation.</i>	• The KGNP area is host to both typical Archaean greenstone gold deposits and 'Kambalda' style, komatiitic hosted, nickel sulphide deposits as routinely discovered and mined in the Kambalda/St Ives district. • The project area is host to gold mineralisation as evidenced by the past mining activities noted above and also nickel mineralisation and elements associated with this nickel mineralisation, such as Cu, Co, Pd and Pt.
Drillhole information	<i>A summary of all information material to the understanding of the exploration results including a tabulation of the following information for all Material drillholes:</i> • easting and northing of the drillhole collar • elevation or RL (elevation above sea level in metres) of the drillhole collar • dip and azimuth of the hole • down hole length and • interception depth hole length	• Drill hole collar location and downhole directional information has been provided for all material drill holes within the body of this, or related previous ASX reports and also within the relevant Additional Details Table in the Annexures of this, or those reports. • Cross sections are often only able to be presented once sufficient pierce points on the same section have been generated and the interpretation sufficiently well advanced to present such sections in a meaningful manner.

Criteria	JORC Code explanation	Commentary
Data aggregation methods	<i>In reporting Exploration Results, weighting averaging techniques, maximum and/or minimum grade truncations (e.g. cutting of high grades) and cut-off grades are usually Material and should be stated.</i>	- Grades have been reported as intervals recording down-hole length and interpreted true width where this estimation is able to be made. - Any grades composited and reported to represent an interpreted mineralised intercept of significance are reported as sample-length weighted averages over that drill intercept. Gold Exploration Results - The Company currently considers that grades above 0.5 g/t Au and/or 1.0 g/t Au are worthy of consideration for individual reporting in any announcement of Exploration Results in additional details tables provided. - Composite grades may be calculated typically to a 0.5 g/t Au cut-off with intervals greater than 1.0 g/t reported as "including" in any zones of broader lower grade mineralisation. - Reported intervals may contain variable widths of internal waste (samples with values below stated cut-off grade) depending on the style of gold mineralisation being investigated however the resultant composite must be greater than either the 0.5 g/t Au or 1.0 g/t Au as relevant (or the alternatively stated cut-off grade). - No top-cuts have been applied to reporting of drill assay results, and no metal equivalent values have been reported. - Where present, historical SIGM drilling in the project area was typically only assayed for Au. Surface rock chip and grab sampling (where relevant) - Only individual rock chip assay results have been released in the past. - Results have not been aggregated. - No metal equivalent values are reported. - Results are from surface outcrops, existing historical sample pit spoils as relevant, and/or surface rock float and no estimate of width or geometry of the sampled medium is provided
Relationship between mineralisation widths and intercept lengths	<i>If the geometry of the mineralisation with respect to the drillhole angle is known, its nature should be reported.</i> <i>If it is not known and only the down hole lengths are reported, there should be a clear statement to this effect (e.g. 'down hole length, true width not known').</i>	- In regard to the gold prospects reported, subject to the stage of maturity and thus understanding of the prospect and target mineralisation, again, if possible, drillholes are designed to intersect target surfaces at approximately perpendicular to the strike of mineralisation. - Earlier stage or conceptual gold targets however may not be sufficiently well understood to allow this to be the case.
Diagrams	<i>Appropriate maps and sections (with scales) and tabulations of intercepts should be included for any significant discovery being reported. These should include, but not be limited to, a plan view of drillhole collar locations and appropriate sectional views.</i>	- The Competent Person decides on the appropriate sectional representation, if one is possible. - The one chosen may not be a cross section, if a longitudinal section or projection is considered more appropriate. - If long plunge extents are present, long projections are often considered the most appropriate format to present most results, especially if there are insufficient drill hole intercepts to present meaningful, true cross sections. - Isometric and plan views are also utilised to place drill results in context if possible. - In regard the gold prospects reported, plan, isometric, long projection and/or cross section views are presented if sufficient data or individual drill intercepts are present to make this meaningful.
Balanced reporting	<i>Where comprehensive reporting of all Exploration Results is not practicable, representative reporting of both low and high grades and/or widths should be practiced to avoid misleading reporting of Exploration Results.</i>	Drill collar locations of Previous Owners Historical drilling and current drilling completed by Lunnon Metals have been previously lodged on the ASX platform and all results of the drilling have also been previously reported.

Criteria	JORC Code explanation	Commentary
Other substantive exploration data	<i>Other exploration data, if meaningful and material, should be reported including (but not limited to): geological observations; geophysical survey results; geochemical survey results; bulk samples – size and method of treatment; metallurgical test results; bulk density, groundwater, geotechnical and rock characteristics; potential deleterious or contaminating substances.</i>	• The KGNP has a long history of geological investigation, primarily for nickel, but also gold to a lesser degree. • Datasets pertinent to the KGNP that represent other meaningful and material information include: • Geophysics - multiple ground and aerial based surveys of magnetic, gravity, Sub Audio Magnetics, electro magnetics, and down hole transient electromagnetic surveys along with more limited 2D and 3D seismic surveys. • Geochemistry - gold and nickel soil geochemistry datasets across the KGNP and rock chip sampling in areas of outcrop. • Geotechnical test work on drill core is carried out by independent consultants MGT involving on-site geotechnical logging of the DD core and off-site rock property testing of selected DD core samples. • Downhole Transient Electro-magnetic (DHTEM) surveys, when conducted, use the DigiAtlantis system and DRTX transmitter. The readings are typically recorded at 2.5m to 10m intervals. The survey used loops ranging from 300m x 200m to 690m x 290m in orientations designed relative to the target and stratigraphic setting. • If required, the Company generally retains ABIM Solutions Pty Ltd (ABIMS) to use the latest generation QL40 OBI Optical Televiwer (OTV) and a customized logging vehicle, to conduct OTV wireline surveys in the project area in select RC or DD holes. • The OTV survey generates an oriented 360-degree image of the borehole wall by way of a CCD camera recording the image reflected from a prism. • ABIMS provide in-house OTV data interpretation techniques which include structural feature classifications along with structural feature dip and dip direction determination. • The OTV wireline surveys in RC holes, if applicable, are particularly useful in defining geological and structural orientation data, data that is otherwise unobtainable from RC drill chips. • Where completed, these OTV surveys can identify the downhole locations of geological and structural features potentially associated with gold mineralisation such as veining and shearing, such that the positions and intensity of these features can be reconciled with the RC chips used by the geologist for geological logging. • If required, ABIMS are also used to collected down-hole imaging data using the latest generation ABI40 Acoustic Televiwer (ATV) and a customised logging vehicle. The ATV wireline survey in DD holes provides down-hole geological definition, geotechnical rock mass characterisation, determination of fracture frequency and orientation, and primary stress orientation. The ABI40 ATV generates an image of the drillhole wall by transmitting ultrasound pulses from a rotating sensor and recording the amplitude and travel time of the signals reflected from the drillhole wall. Data is transferred back to the surface via a wireline in real time. Such data collected is used by the Company's geologists in support of deposit geological and structural modelling and by geotechnical consultants for geotechnical assessment purposes. • If required, Southern Geoscience Consultants Pty Ltd (SGC) provide an ultrasonic velocity meter for the collection of velocity data measurements on DD. Data from this coupled with density measurements will provide acoustic impedance information, enabling the reflectivity in the seismic section to be tied to the geology in the borehole. Commentary specific to previous metallurgical test work • Detailed metallurgical test work has been completed by the Company at its Lady Herial deposit to simulate the operating conditions at the SIGM Lefroy Plant.

Criteria	JORC Code explanation	Commentary
Other substantive exploration data (continued)		• By commercial agreement with SIGM in the OPA, the metallurgical recovery factor has been set at 91.0% on the basis of this extensive test work. • The average metallurgical response from the test work was an overall gold recovery of 91.4% (for a 12-hour residence) and 94.6% (24-hour residence) at P80 passing 150µm. • The results of this test work have been previously reported on 17 February 2025 and 14 August 2025. • Given the extensive direct experience of the Competent Persons at St Ives, exploring and mining multiple deposits of similar mineralogical characteristics, they consider it reasonable to assume that other nearby and local prospects, will display a similar metallurgical response to Lady Herial itself. • Therefore, both the principal and relevant Competent Persons have concluded that there are reasonable prospects that the gold mineralisation reported will also be amenable to treatment at the gold processing facilities closest to the KGNP i.e. Lefroy. • More detailed, prospect specific test work will be conducted should any target progress through the relevant stages of exploration maturity.
Further work	<i>The nature and scale of planned further work (e.g. tests for lateral extensions or depth extensions or large-scale step-out drilling).</i>	• Since the Company's IPO through to end of May 2026, over 140,000m of diamond, RC or aircore drilling has now been completed at FBA and SLF, initially focused on nickel exploration until a shift of focus to gold in early 2024. • Nearly 33,000m of historical core has also been reprocessed in the Company's Historical Core Program (HCP) over that same period, for a total of 170km combined. • All Company work programs are continuously assessed against, and in comparison to, ongoing high priority programs elsewhere at the KGNP. • This report relates to an Exploration Target. Activity to test the Exploration Target will involve early-stage exploration, which is an iterative process with assay, geological, geochemical, geophysical and litho-structural observations and results all contributing to a continuous assessment of the merits of any particular target, and how, or whether, to continue to pursue further data collection and further definition, potentially by continuing to drill. • The Exploration Target also refers to local scale drilling at various stages of maturity. • Subject to further drilling results and success of the various prospect tests, future metallurgical and geotechnical assessment will be required and infill drilling of any particular prospect or target will be required prior to seeking to report a MRE. • Thereafter, subject to positive ongoing results and external market and price variables, updates and future additions to the Company's MRE may then form the basis for development studies that may lead to the future declaration of a Probable Ore Reserve from those portions of the MRE at the Indicated (or higher) classification. • Any such Ore Reserves then in turn may form the basis of technical and economic studies to investigate the potential to exploit those gold (or if/when relevant nickel) deposits in the future.
